The publication of the series of volumes on the Harriman Alaska Expedition of 1899, heretofore privately printed, has been transferred to the Smithsonian Institution by Mrs. Edward H. Harriman, and the work will hereafter be known as the Harriman Alaska Series of the Smithsonian Institution.

The remainder of the edition of Volumes I to V, and VIII to XIII, as also Volumes VI and VII in preparation, together with any additional volumes that may hereafter appear, will bear special Smithsonian title pages.

PREFACE

The present volume comprises two papers: one on the Land and Fresh Water Mollusks of Alaska, by Dr. Wm. H. Dall; the other on the Hydroids of the Expedition, by Prof. C. C. Nutting. Dr. Dall’s paper has not been previously published; Professor Nutting’s appeared in the Proceedings of the Washington Academy of Sciences in May, 1901. The number of new Mollusks here described is twelve; of new Hydroids twenty.

C. Hart Merriam,

Editor.

LAND AND FRESH WATER MOLLUSKS OF ALASKA AND ADJOINING REGIONS
NOTE

The following memoir has been prepared to bring together and modernize the data existing in the literature, and to combine it with the new material obtained by the Harriman Expedition and such as was accessible elsewhere from the same region. In order to accomplish this, and because of the uniformity of boreal faunas all round the northern hemisphere, it has been necessary to examine the entire boreal fauna of North America, Greenland, and the adjacent parts of eastern Siberia.

The material examined has been that collected by the Harriman Expedition; that obtained by the writer during explorations in Alaska from 1865 to 1885, and now in the National Museum; collections from various collaborators of the Museum, members of the Navy, the Revenue Marine, and the Geological Survey of the United States; and certain material borrowed for examination from various sources. On the whole, though the collection is not remarkably large, it is probably the largest and most complete, for the region, ever brought together.

The text figures have been generously lent by the Smithsonian Institution.

I am indebted to Mr. Bryant Walker, Dr. J. F. Whiteaves of the Dominion Geological Survey, Dr. H. A. Pilsbry, of the Academy of Natural Sciences, Philadelphia, and numerous other correspondents, for advice and assistance; and to the authorities of the U. S. Geological Survey, the Dominion Geological Survey, the Smithsonian Institution, and the U. S. National Museum, for facilities for study and access to collections, for all of which I am deeply grateful.

WM. H. DALL.

LAND AND FRESH WATER MOLLUSKS OF ALASKA AND ADJOINING REGIONS

BY WILLIAM HEALEY DALL

GENERAL DISCUSSION AND RESULTS

The first object of this work is to sum up the known molluscan fauna of the land and fresh waters of Alaska. This has involved an examination, not only of the species obtained within the political boundaries of Alaska, but also those of the adjacent region to the west, east, and south. The result is that, for North America north of latitude 49° North, the work includes a summary of our present knowledge of the mollusks, deduced in part from the literature and in larger part from material actually examined. To this is added a briefer examination of the mollusk fauna of the adjacent parts of eastern Siberia which has to some extent modified that of Alaska. As a whole the work may be regarded as forming a synoptic manual of the boreal land and fresh water mollusks of the western hemisphere.

I. SUMMARY OF THE DISTRIBUTION OF FRESH WATER SPECIES IN ALASKA AND ADJACENT REGIONS.

It was thought best to tabulate the species of rivers and lakes according to the drainage systems in which they are found. Of course these systems are not geologically ancient, and it is even probable that some existing species of the Mississippi system were trapped by the changes of level which, according to Gen. G. K. Warren, U.S.A., secured, for the Red River of
the North, part of the channels which earlier discharged into the Gulf of Mexico by way of the Mississippi. It is probable, for the region under review, that the entire molluscan population was exterminated or driven south during the Glacial epoch, and that we now have to do with immigrants from the south whose distribution has taken place since that time.

In the following tables all doubtful species are omitted, so that the fauna tabulated, if not complete, is at least well established so far as it goes.

The following areas are represented in the successive columns of the table:

**Asia.** — This column indicates those species known also to inhabit the eastern portion of Siberia, Kamchatka, and the Chukchi Peninsula, together with the Commander Islands, which are obviously populated from the Asiatic shores.

**Yukon.** — This system includes the entire drainage basin of the Yukon and the tundra north of it, as well as the area drained by the Kuskokwim River, or all of Alaska north, northwest, and westward of the Alaskan Range, as well as the area behind the Coast Ranges and between them and the northward extension of the Rocky Mountains, drained by the Yukon and its tributaries.

**Alaska.** — This system includes all of the Aleutian Islands, the area on the Alaska Peninsula and continent between the Coast Ranges and the Alaskan Range and the Pacific north of latitude 54°. This system and the following one are really continuous, the Alaskan being really only the northward extension of that here designated as the Pacific system.

**Pacific.** — This includes the coast drainage of British Columbia, the basins of the Fraser and Columbia rivers, the coastal part of the State of Washington, and the northern part of Idaho and Montana west of the Selkirk Range and its more southern equivalents in the Rocky Mountain region.

**Mackenzie.** — This vast system includes the basin drained by the Mackenzie River and its tributaries, covering northwest Alberta, northeastern British Columbia, the northwestern two thirds of Athabaska, and the Mackenzie district.
Hudson Bay. — This system, the largest of all, comprises the entire area draining into Hudson Bay, including Keewatin, the southeastern corner of the Mackenzie district, eastern Athabaska, the whole of Saskatchewan, the southeastern two thirds of Alberta, Assiniboia and Manitoba, the drainage area of the Red River of the North in the Dakotas and northeastern Minnesota, all of Ontario, Quebec, and Ungava north and west of the 'Height of Land.'

Canada. — This system comprises the drainage of the St. Lawrence and the Great Lakes south and east from the Height of Land, including the island of Anticosti.

Labrador. — This comprises the area draining into Ungava Bay and the Atlantic north of the Straits of Belle Isle and the Height of Land, being the Labrador coast and the northeastern part of the Ungava district of the Dominion of Canada.

A few species are noted from Greenland; when peculiar to Greenland, or found in Greenland and also on the continent, the species have been entered in the Labrador column but distinguished by an asterisk.

The vast territories included in these drainage systems are, it is true, only partially and imperfectly explored for mollusks. Yet certain portions of them are tolerably well known, and the uniformity imposed on the fauna by its high northern position and unvaried conditions leads to the belief that while much is yet to be known in tracing out the details of distribution, little is to be expected in the way of absolutely new species, even from this immense territory still to be explored. It would be rash to conclude that nothing new remains to be found; but it certainly behooves us to be moderate in our expectations.

It is probable that new additions will be made from among the ranks of the smaller species, such as Corneocyclus (or Pisidium), Vertigo, and the more minute Helicidae. Perhaps a considerable number of the more southern forms which are known to approach the boundary will eventually be found to pass beyond it; and other additions to the list will result from the more careful discrimination of similar or closely allied species.

II. SUMMARY OF THE DISTRIBUTION OF THE LAND SHELLS OF ALASKA AND ADJACENT REGIONS.

I have summarized the distribution of the fresh water shells by drainage areas, as perhaps the least objectionable method of connecting the facts of distribution. But the land shells require a somewhat different treatment, since their distribution has nothing to do with currents of water, though sometimes a snail may be carried in the spring freshets under the bark of a floating log, and by rare chance survive to be stranded by the falling waters somewhere down stream. A certain amount of movement of the minute forms may result from the distribution by high winds of dead leaves and other light material to which the smaller land shells are accustomed to adhere. Pieces of ice from smaller brooks carried by freshets may also convey a certain distance and deposit, when stranded by falling water, pieces of bark or leaves containing snails or their eggs. Such chances are too rare to be made much account of, and doubtless the distribution of our smaller snails is brought about in the main by the slow movement of individuals.

The Pulmonate fauna of Alaska is composed of four elements: contributions from the faunas of Asia, of the Pacific Coast of America, of the Canadian (or Hudsonian) region, and of the circumboreal or common subarctic fauna of the whole northern hemisphere.

In tabulating the distribution of the species a column may be reserved for each of these elements; the circumboreal column being headed 'Europe.' A column may be reserved for Greenland, and another for the approximate highest north latitude which the species is known to attain. This means for the snail not so much differences of temperature corresponding to latitude, as differences of period in activity, which diminish as one proceeds northward. Snails at Point Barrow must remain in a state of hibernation at least nine months in the year, and I suspect that this more probably brings a limiting strain on the vitality of the organism than would the mere occurrence at times of a specially low temperature.

### III. SUMMARY OF THE MOLLUSK FAUNA OF NORTHEASTERN ASIA.

The land shell fauna of the northeast extremity of Asia has little individuality, but represents a mingling of the depauperated extremes of the faunas of northeast China, and of Europe, with that series of species which is sometimes called the circumpolar or circumboreal fauna.
Much of the apparent poverty of the fauna may be due to insufficient collecting, but even when the most generous allowance for this factor is made, it still remains certain that the molluscan population is far less in variety than might reasonably be expected.

The Palearctic fauna of Europe appears to extend clear across northern Asia, losing a large proportion of its species on the way, until (if the circumforeal species be excluded) only about thirty species reach the headwaters of the Lena and the barrier of the Stanovoi Range. A very remarkable local fauna exists in the great ‘relicten-see’ of Siberia, Lake Baikal, but it does not appear to have tinctured the east Siberian fresh water fauna outside of that lake, to any appreciable extent. It is possible that the comparatively recent emergence of a large part of eastern Siberia from the sea, and the presence of the vast desert region to the south and west, may enter into the explanation of this sparse shell fauna, as well as of some of the peculiarities of the Baikal fauna.

Southeast of the Stanovoi Range we find between the mountains and the sea, the valley of the Amur and several smaller valleys, such as the drainage basins of the Ud and the Tugar. To the southwest the sources of the Amur emerge from the deserts of Gobi and Dauria, and along the line of these water courses has crept a certain number of molluscan forms intimately related to or identical with those of Mongolia, China, and the Orient. This forms the second element of the fauna of northeast Siberia. The number of purely endemic species is remarkably small, and a portion of those claimed to be of this character are probably mere local mutations of widespread Palearctic forms already known. Yet it would seem as if a more thorough exploration must add largely to the species now known, and it is almost incredible that the luxuriant fertile valleys of Kamchatka and the innumerable streams and lakes of that country should not be well populated with mollusks.

There are few species which seem to be common to the shores of Bering Sea, both Asiatic and American, such as Succinea chrysis, Punctum conspectum and Anodonta beringiana. There
is one local species, *Eulota weyrichi*, known only from Sakhalin Island;¹ and another, *Helicigona sub-personata*, from the valley of the Ud. Three forms of *Vivipara* (of which two are probably variants of Chinese forms) are the only local species of the vast Amur valley, or drainage, not known from other regions. Nine specially Kamchatskan species have been described, but about half of them are doubtfully distinct.

The total number of land and fresh water mollusks known from the Amurland, Sakhalin, Kamchatka, the Chukchi Peninsula, and the Asiatic coast north of the Amur and east of the Stanovoi Range, is only eighty-two.

Of these, thirteen are circumboreal species and twelve are supposed to be locally peculiar. The remainder are distributed as follows:

</tbody>
</table>

Of these erratic species a few may be especially mentioned. *Margaritana margaritifera*, as is well known, is absent from the whole of the great northern central region of North America, though it appears in the lower Saskatchewan, the sources of the Missouri, and in eastern Canada, while on the Pacific it ascends at least to latitude 56° N. In eastern Asia it is known from Kamchatka, Sakhalin Island, the upper portion of the Amur basin, and southern Mongolia, but I find no authoritative record of it thence westward to northern and middle Europe. Schrenck did not find it on the lower Amur.

*Physa fontinalis* is reported from the upper Amur and (in a duck’s crop) the desert of Dauria, but is not known from Siberia proper, though common in Europe. There is an entire absence of typical *Physa* throughout east Siberia, so far as reported; and only one species of *Ancylus* or *Unio* is known from east of the Yenisei River of Siberia.

¹ In a recent paper Hugh Fulton describes *Eulota flexibilis* and *E. (Euhadra) fascina* n. sp. as “probably” from Sakhalin Island; but this seems to me very doubtful when we consider the size of these shells and the fact that the warmest part of Sakhalin has a mean annual temperature of only 33.4° F. and for six months of the year the mean is below the freezing point. The shells are more probably from Yesso.
Aplexa hypnorum is known from northern Europe, western Siberia, and the Chukchi Peninsula, but has not been reported from eastern Siberia, or the Amur, though abundant in Alaska, and reaching on the Taimyr Peninsula to 73° 30' north latitude.

Zoögenites harpa is known from northern Scandinavia in Europe; from northeastern America, the Hudson Bay territory and Southeastern Alaska, in America; but in Siberia it is recorded only from the easternmost margin, the Chukchi Peninsula, Bering Island, Kamchatka and the lower Amur. These singularities of distribution must await much more extended knowledge before they can be adequately discussed, but it is believed that to some extent they are due to the transgression of the sea, or of glacial ice, over part of the area in which a species might naturally be expected to occur, thus delaying the occupation of the entire region by the species concerned.

In the following table the distribution is indicated by the headings of the six columns. Varieties are not included when the typical form appears in the table.

Column 'Eur.' includes those forms recorded as found in Europe, including the whole of European Russia and the Caucasus.

Column 'Lena' includes the drainage of the Lena and the whole of Siberia from the Lena westward to the Ural Mountains. It should be noted that a number of species which reach the Lena from the west do not cross the Stanovoi Range.

Column 'Amur' includes the Amur drainage basin, the Island of Sakhalin, and the smaller drainage areas between the Amur and the Stanovoi Range.

Column 'China' includes those forms which, having their center of distribution in China or Japan, extend their range to the drainage basin of the Amur, though often reaching only the southern and eastern part of it.

Column 'Kam.' indicates species belonging to the area included in the Kuril Islands, the Commander Islands, Kamchatka proper, the Chukchi Peninsula, and northeastern Siberia east of the Stanovoi Range and north of Aian.

Column 'Am.' includes those forms found in the Aleutian Islands, northern and northwest America, which also occur on the Asiatic side.
The nomenclature is brought up to date as far as possible. The absence from the list of certain names which appear in the memoirs of Schrenck, Middendorff, and others, is only apparent; they are really present under their revised names. I have accepted Simpson's determination of the Naiades, and retain, for the variety of *Unio pictorum* which occurs in eastern Siberia, the early name adopted by Rößmässler from Ziegler's MS., rather than the very recent one which has been proposed by Westerlund. The list of Amurland mollusks in the Vega Expedition report includes several which belong only to the Lena province or western Siberia and do not occur on the Amur.

The material examined from which this and the preceding tables have been prepared, has been derived from several sources. The collections of the National Museum containing the boreal shells upon which the work of W. G. Binney was partly founded, have been of great help. I have also had the kind cooperation of Dr. J. F. Whiteaves of the Geological and Natural History Survey of Canada. My own collections from 1865 to 1899 in Kamchatka and Alaska have furnished much material. I have also had interesting collections from Messrs. Randolph, McGregor, Stoney, Hepburn, Arnheim, Krause, Palmer and others who have visited Alaska for pleasure or in the Government service. The collections actually made during the Harriman Expedition were more interesting than extensive, but have helped considerably, especially those due to the energy of Prof. Trevor Kincaid, of Seattle, while engaged in his entomological researches.

### IV. Conclusions in Regard to the Alaskan Fauna.

The fauna of Alaska, so far as the land and fresh water shells considered in this paper enable us to judge, is composite. The mollusks are characteristic especially of two, and to a much smaller extent of two other, faunas. The former are limited by topographic features. Thus the fauna of boreal Canada, in constantly diminishing number of species, is extended to the northwest, north of the Alaskan Range to Bering Sea on the west and the Arctic Coast on the north.

In like manner the fauna of the northern part of the Pacific States is extended west of the ranges which in the north represent the Rocky Mountains, and between them and the sea, northward into British Columbia and thence westward into Alaska, south of the Alaskan Range, until the last representa-
tives of the fauna disappear among the islands of the Aleutian chain. In British Columbia a few species belong to the valley region between the Rockies and the Cascade Mountains, and do not reach the sea coast, but these are too few to modify perceptibly the general rule, and as a matter of fact they, like the valleys themselves, soon disappear after crossing the 49th parallel.

Very much the same thing is true of the birds, as I was able to demonstrate some thirty-five years ago; and even the marine mollusks of the Alaskan coast form a somewhat analogous assembly.

The other two faunas concerned are those (1) of Asia, or rather eastern Siberia, that part of Asia nearest to Alaska, and (2) the Holarctic or circumboreal group of species which are common to the entire boreal zone and characteristic of it, though rather few in number.

In referring to the Canadian fauna it will of course be clearly understood that the fauna of that part of Canada discussed in this paper and not the entire fauna of the whole Dominion is meant. With this reservation we may proceed to discuss the matter from the statistical point of view.

One hundred and forty-seven species or strongly marked varieties are enumerated here from the Canadian region as above limited, and fifteen other forms are mentioned which though not known to cross the boundary yet in all probability will eventually be found to do so. By reference to the preceding tables the extension of each species will be found recorded, and the particular localities as far as discoverable are enumerated in the following text. Forty-one species are known from the Alaskan extension of this fauna north of the Alaskan Mountains, or characteristic of that part of the territory. Half of these are circumboreal or Holarctic forms.

The fauna of British Columbia, or the British Columbian extension of what I many years ago designated the Oregonian fauna, comprises seventy-five species, so far as known, to which in all probability should be added some thirty-eight which are known to approach the parallel of 49° from the south and
which probably cross it, making a probable total British Columbian fauna of one hundred and thirteen forms. Considering the very small area occupied by this assembly, when compared with the vast expanse populated by the Canadian fauna, the number is notable. Doubtless in both cases future exploration will add a reasonable number not now enumerated or still undescribed by naturalists.

The contributions from the Columbian assembly to the fauna of Alaska south of the Alaskan and west of the Cascade Ranges comprise thirty five known and six probable species, a total of forty one forms probably inhabiting the area referred to. Some of these, however, are common to northern Alaska also, making the proper deduction for which we find sixty five species of land and fresh water mollusks known to inhabit the territory of Alaska, with six or seven more which are likely with further exploration to be credited to it in addition to those now known, even if no undescribed species turn up.

The vast unexplored areas, the uncertainties connected with lists of obsolete names and doubtful identifications, the doubt as to what may be considered specific limits in groups of notorious variability, and especially the frequent absence of specimens from which better deductions might have been drawn than were possible from the extant literature, have all contributed to the difficulties under which this memoir has been prepared. Those who have done work on similar lines will understand, and will view without undue severity, the imperfections which the author only too well realizes, and yet which it was out of his power, in the present state of our knowledge, to avoid. It is hoped, however, that this summary will make the path somewhat easier for those who follow him, and contribute a reasonable share to the better appreciation of the facts of Nature of which it treats. And if, among the hardy explorers of whom our neighbors of Canada are justly proud, this paper serves to stimulate an increased interest in the subject, the author will feel that his endeavors are amply repaid.
The following annotated catalogue is intended to contain a list of all the species known to inhabit the designated region, with the addition of a few which approach the boundary so closely that it is highly probable that on further search their range will be found to cross it. Names of species belonging to the latter category are preceded by an asterisk.

It is intended that the synonymy which follows the name shall exhibit references to the original description of the species, to a good figure, and to the work in which the synonymy, if at all complicated, may be found most fully set forth. The synonymy of some of the genera mentioned seeming to be in great need of elucidation, an attempt has been made to clear it up. In other cases, where the work has elsewhere recently been done, the generic name and authority alone are cited. For the Helicidae and associated forms I have depended upon the arrangement of Dr. H. A. Pilsbry, the acknowledged master of the subject; and for the Naiades, in like manner, on the 'Synopsis' of Mr. Chas. T. Simpson. Some of the other groups I had previously worked up elsewhere, and have utilized the results in this catalogue.

After the synonymy it has been attempted to state the range of the species geographically, in general terms. This statement is followed by a citation of special localities within the designated region from which the species has been reported, and in those cases in which the writer has verified the report by the examination of specimens, the name of the locality is followed by an exclamation mark.

These data are exemplified or explained by notes following the details of geographical distribution in a separate paragraph.

The data in many cases have been taken from the literature, a bibliography of which concludes this paper; and it follows that the present writer assumes no responsibility for the identifi-
cation of species so derived. Usually, however, there is no particular reason for doubting the accuracy of these identifications. It has not seemed necessary, in most cases, to cite the authority for the locality, a course which would have unduly increased the bulk and diminished the clearness of the distributional statement. The authority, as a rule, can easily be found by reference to the bibliography. In a few cases, however, it has seemed desirable to include in parentheses the authority for the locality cited, especially when the latter seemed unusual or debatable.

Family HELICIDÆ.

Genus Helix (L.) Pilsbry.

Helix (Cepaea) hortensis Müller.

Range. — Europe from Hungary to the Atlantic between middle Scandinavia and the Pyrenees, northeastern border of North America. Labrador; Newfoundland; Anticosti Island! Barachois, Gaspé; Cape Breton Island! Halifax! Casco Bay, Maine! shore of Cape Ann and adjacent islets, Mass.! Nantucket Island! Pleistocene deposits near Portland, Maine!

A single specimen was once found in Greenland, but was doubtless imported accidentally. The prevalent type is light yellow, without or with only faint traces of bands. The former is Binney's *H. subglobosa.*

The wide distribution of the species, often on uninhabitable islets off a coast little frequented, and its presence, which I have verified, in the glacial Pleistocene of Maine, tend to confirm the view that it is a prehistoric immigrant if an immigrant at all.

**Fig. 1. Helix hortensis var. subglobosa Binney.**

I have seen most of the commoner varieties which are prevalent in Europe, but it is obvious to the collector that the brighter colored types with sharply define dark bands form an insignificant proportion of the American specimens; while the shells as a whole seem smaller than the average dimensions of European specimens.

1 The exclamation point indicates that specimens from this locality have been seen by me and verified as correctly identified.
Helix (Arianta) arbustorum L. has been noted as an introduced species, at St. John, Newfoundland, just outside of our region, by Whiteaves.

Genus Epiphragmophora Doering.

Epiphragmophora fidelis Gray.

Helix nuttalliana Lea, Trans. Am. Phil. Soc., vi, p. 88, pl. xxiii, fig. 74, 1839.

Epiphragmophora fidelis Pilsbry, Class. Cat. N. Am. Landsh., p. 4, 1897.

Range.—Northern California to Sitka, Alaska.

Sumas Prairie, Fraser River valley, B. C. (common to 6,000 ft., J. K. Lord); Chilliwak Lake, B. C.; Victoria! Nanaimo! Comox! on Vancouver Island; Growler Cove, Broughton Strait; Union Bay! False Bay, Lasqueti Id.; Malaspina Inlet; N. point Texada Island, British Columbia; Sitka, Alaska!

The Sitkan and Columbian specimens are apparently not markedly different from those collected further south, and pass through the same color variations. If there is any difference it is that the northern specimens are a little smaller and exhibit no tendency to pilosity. The two specimens obtained at Sitka were found near the Hot Springs. There is no evidence in regard to the distribution of the species north of Sitka, but it would not be surprising if it were eventually found to extend on the outer islands as far north as Cross Sound.

Genus Zoögenites Morse.

This group has been united with the Acanthinula of Beck, of which, it would seem, little is known but the shell, while we have, thanks to Morse, a very satisfactory account of our mollusk. I prefer therefore to defer any consolidation with Acanthinula until it is shown to be necessary. The information to be had from Moquin Tandon in regard to Acanthinula aculeata is unsatisfactory and insufficient. Westerlund (1902) has proposed a genus Aulaca to contain both (prior) genera!

Zoögenites harpa Say.

Helix harpa Say, Rep. Long's Exped., ii, p. 256, pl. xv, fig. 1, 1824; Biney's Say, p. 29, pl. lxxiv, fig. 1.

Helix amurensis Gerstfeldt, Mém. des. Sav. étr., ix, p. 517, pl. 1, figs. 26, a-c, 1859.

Zoogenetes harpa auct. plur.

Range.—Northwestern Scandinavia, northeastern America, British America near Hudson Bay, Southeastern Alaska, and the easternmost margin of Siberia.

Konyam Bay, eastern Siberia; Avacha Bay, Kamchatka! Bering Island, Commander group; lower Amur River region. Klehini, Chilkat Inlet and valley, Alaska; English River, Manitoba! Moose Factory! Hudson Bay; Minnesota; Gaspé; New England; etc.

The peculiarities of the distribution of this curious little mollusk are referred to in the general discussion of the fauna of northeastern Asia.

Genus Vallonia Risso.

Chilostoma (sp.) Fitzinger, Syst. Verz., p. 98, 1833.

Circinaria (sp.) Beck, Index Moll., p. 23, 1837.

Glaphyra Albers, Heliceen, p. 87, 1850.

Vallonia pulchella Müller.

Fig. 2. Vallonia pulchella, ."
Range.—Europe; North Africa, southern and western Siberia to the Amur; Madeira; the Azores; eastern North America from Manitoba to Florida and Montana to Nova Scotia.

Manitoba, at Winnipeg and Pembina; north to the Saskatchewan (Richardson). Introduced? in California.

Although Risso’s figure of *V. rosalia* represents a perfectly smooth shell, his diagnosis calls for one with elevated lamellae; it is probable therefore that he regarded the present species and *V. costata* as varieties of a single species.

**Vallonia costata** Müller.

*Helix crenella* Montagu, Test. Brit., i, p. 441, pl. xiii, fig. 3, 1804.

*Helix pulchella* var. Rössmässler, vii, p. 6, fig. 439, 1838.—FéruSSac, Hist., pl. lxix e, figs. 15–17, 1821.

**Range.**—With *V. pulchella* in Europe and Asia; in America in the northern States and northward from Kansas and Colorado.

Manitoba (Hanham).

This species has been so constantly confused with the other costate species and with *V. pulchella* that it is hardly practicable to determine its true range from the literature.

**Vallonia gracilicosta** Reinhardt.

**Range.**—Rocky Mountain region, westward and northward from the upper Missouri.

Manitoba, at Winnipeg; in Alberta at Laggan. Red Deer Olds and McLeod.

Easily recognized by its very prominent, not crowded, very oblique lamellae.

**Vallonia albula** Sterki.

**Range.**—Eastern Canada to British Columbia.

Quebec; Manitoba; Vancouver Island.

**Vallonia asiatica** Nevill.

**Range.**—Central Asia, Tibet. Alaska.
Pyramid Island, Lynn Canal, Alaska, fide Reinhardt.
This form, collected by Dr. Krause, was identified by Dr. Reinhardt with Nevill's species and is included here solely on his authority, as I have not seen specimens.

Genus Polygyra Say.

Polygyra devia Gould.

*Polygyra devia* PILSBRY, Class. Nat. Am. Landsh., p. 11, 1897.

Polygyra columbiana Lea.

*Polygyra columbiana* PILSBRY, Class. Nat. Am. Landsh., p. 11, 1897.

*Range.* — Monterey Bay, California, to Yakutat Bay, Alaska, in the moist wooded region west of the Rocky Mountains.

Mountains of Idaho, western Montana and Washington; Vancouver Island at Victoria! Nanaimo and Nootka; British Columbia mainland on banks of Fraser River (Lord) and Skeena River! (Osgood); Hbledown and Pender Islands, Johnstone Strait; Union Bay! Port Simpson; and Cumshewa Inlet, Queen Charlotte Islands! B. C.; in Alaska at Cape Fox! Annette Island, Killisnoo, Sitka! Lynn Canal; Biorka Island! Chilkat valley! Lituya Bay! Yakutat!

There are several varieties of this widespread and familiar species. First, the type, subconic rather elevated and small, with narrow reflexed lip. Lea's specimen was decorticated and showed no signs of the hairs with which the shell is usually covered, but this was accidental; some specimens normally show hardly a trace of the hairs which are usually so conspicuous. The second variety, *P. labiosa* Gould, is larger, more depressed relatively, with a broader, somewhat flexuous reflected lip. This form is more prevalent in the interior of Washington, Idaho, etc., and more often has a parietal tooth or trace of a tooth. The variety *santarcruczensis* is in form more like the type but much smaller, thin, lighter colored, with a sparser pelage, and about half the specimens have a trace of a parietal tooth, while in a lot of about seven hundred *columbiana*, from Sitka, I found only one specimen
which had any parietal tooth. The mountain forms from California, if not hybrids, are so very different from the hairy coast or lowland shells that one is tempted to regard them as distinct; they frequently are rough, hairless, with heavy lip and well marked parietal tooth. A young specimen of the typical form, collected near Yakutat Village by the Harriman Expedition, is reversed.

Some specimens of this and another species, both of which are confined to wooded regions so far as authentically known, were once sent me as from a point considerably north of Yakutat and from the treeless region. I do not believe these shells were correctly labelled, and hence have not included them in the list of localities. My own impression is that the extension northward of this species and *Circinaria vancouverensis* has been prevented by the wide stretch of glacial area just north and west from Yakutat Bay. I have searched for this species at Prince William Sound and Cook Inlet, in suitable situations, but without success.

**Polygyra townsendiana** Lea.

*Range.*—Puget Sound region and south (to northern California?). Seattle, Wash.; Lake Chilliwak and Sumas Prairie, British Columbia.

Eastward from the moist coast region the following species occurs and is sometimes regarded as a depauperate form of *P. townsendiana*.

*Polygyra ptychophora* Brown.

*Arionta townsendiana* var. *ptychophora*, Binney, Man. Am. Landsh., p. 129, fig. 102, 1885.

*Range.*—Western Montana (at Deer Lodge) westward through northern Idaho to Spokane, Wash., and to The Dalles, in northern Oregon.

It is possible that this form may hereafter be found on the northern side of the boundary.

**Polygyra germana** Gould.

*Stenotrema germanum* (Gould) Binney, Man. Am. Landsh., p. 114, fig. 82, 1885.

*Range.*—Northern California, through the Puget Sound region to British Columbia.
LAND AND FRESH WATER MOLLUSKS

Astoria, Oregon! Victoria, Vancouver Island; Chilliwak Lake, British Columbia.

A variety *megasoma*, more than four times the size of the typical *germana*, but otherwise quite similar, is occasionally found; some from northern California (Stearns) are in the National Museum.

**Polygyra monodon** Rackett.

— Morse, Am. Nat., 1, p. 151, figs. 12, 13, 1867.

— Binney, Land and Fw. Sh. N. Am., 1, p. 120, figs. 200-205, 1869.

**Range.**— Eastern United States, east of the plains region, from Texas to Minnesota and northward. Moose Factory, James Bay!

**Polygyra albolabris** Say.

**Range.**— Eastern United States, from Georgia and Arkansas northward to the Saskatchewan.

Lake Superior region; Lake Winnipeg, Manitoba; and northward to the Saskatchewan River (Richardson).
Family PUPIDÆ.

Genus Strobilops Pilsbry.

7. Animal from above.  8.  9. Showing internal lamellæ.

Figs. 7–9. Strobilops labyrinthica (magnified).

Strobilops labyrinthica Say.

Range.—Eastern United States, from Texas northward to British America. Carberry, Manitoba; Moose Factory, James Bay!

Genus *Bifidaria* Sterki.

Bifidaria armifera Say.

Range.—The United States east of the Rocky Mountains, and Canada.

Red Deer, Alberta; Brandon, Manitoba.

Bifidaria contracta Say.

Range.—Eastern North America from Mexico to British America, east of the Rocky Mountains. Carberry, Manitoba.
Bifidaria holzingeri Sterki.

Bifidaria holzingeri Pilsbry, Class. Cat., p. 19, 1898.

Bifidaria pentodon Say.

Fig. 12. Bifidaria pentodon (magnified), showing variations in aperture.

Range. — Eastern United States from Texas to British America; southeastern Nevada, Quebec; Ontario; Manitoba (rare); Alberta, at Laggan.

Genus Pupilla (Leach) Turton.

Pupilla blandi Morse.

Pupa blandi Binney, Land and Fw. Sh. N. Am., i, p. 235, fig. 402, 1869.

† Pupa signata Westerlund, 1885, not of Mousson.

Range. — Upper Missouri, Rocky Mountains; New Mexico to Colorado; Canada; Red Deer, Alberta.

Pupa signata was described from the Caucasus, and its inclusion by Westerlund in a list of American Arctic species is probably an oversight.

Pupilla muscorum Linné.

Turbo muscorum Linné, Syst. Nat., ed. x, p. 767, 1758; ed. xii, p. 1240, 1767. — Hanley, Shells of Linn., p. 352, pl. iv, fig. 6, 1855.

Pupa muscorum var. bigranata Rüssmüller, fide Westerlund.

Pupa badia Adams, Boston Journ. Nat. Hist., iii, p. 331, pl. iii, fig. 18, 1840.

Pupa badia Morse, Journ. Portland Soc. N. Hist., i, p. 37, figs. 89-91, pl. x, fig. 92, 1864.

FAMILY PUPIDÆ

Pupa (Pupilla) muscorum Pilsbry, Nautilus, xi, p. 118, Feb., 1898.  
Pupa sublubrica Aucey, fide Binney.

Range. — Europe. In America, New England and Canada; Anticosti; the northern United States as far west as Montana, alpine

(8,000–9,000 feet) in Colorado, Utah and Nevada; northward in British America.

Laggan, Alberta; Anuk, Alaska.

Genus Vertigo Müller.

Vertigo hoppii Möller.

Pupa (Vertigo) hoppii Mörch, Am. Journ. Conch., iv, p. 30, pl. iii, figs. 6–9, 1869.

Range. — Greenland (Ungava, Labrador?).

The references to this species as found in Alberta and Anticosti are doubtless based on a different species, as is Binney’s figure on page 235 of the Land and Fresh Water Shells, part i.

Vertigo modesta Say.

Range. — North America from New England to California and northward. Loess of Iowa.

This is the most abundant and widely distributed species in the north country. I have very little doubt that *V. borealis* Morelet, from Kamchatka and Bering Island, is merely a variety of this species.

*Vertigo columbiana* Sterki.

Range. — Douglas County, Oregon, and northward to Washington, Vancouver Island, and St. Paul Island, Bering Sea!

Resembles *V. gouldii* but wants the basal fold. A variety occurs in Utah. The St. Paul specimen was identified by Dr. Sterki.

*Vertigo gouldii* Binney.

Fig. 17. *Vertigo gouldii* (magnified). Fig. 18. *Vertigo bollesiana* (magnified).

*Vertigo gouldii* Morse, Am. Nat., 1, p. 669, fig. 60, 1868. — Journ. Portland Soc. N. Hist., 1, p. 38, fig. 95, pl. x, fig. 96, 1864.

Range.—Northern United States east of the Rocky Mountains and northward.

Ottawa, Ontario; Manitoba; Upper Missouri at Fort Berthold; Helena, Montana.

The variety arthuri is catalogued from Arctic America by an oversight, in Binney’s Third Supplement, p. 185. It is really from the Little Missouri in Dakota.

Vertigo ventricosa Morse.

Vertigo ventricosa Morse, Am. Nat., 1, p. 966, figs. 61, 62, 1868.
Vertigo ventricosa elatior Sterki, Nautilus, xi, p. 120, Feb., 1898.
Vertigo approximans Sterki, fide Pilsbry.

Range.—Quebec and Maine to Illinois and Alberta; Manitoba; variety elatior at Laggan, Alberta.

Vertigo binneyana Sterki.

Range.—Rocky Mountain region from Albuquerque, New Mexico, to Manitoba.

Seattle, Wash.; Helena, Montana; Winnipeg, Manitoba.

Fig. 19. Vertigo ventricosa (magnified).

Figs. 20–22. Vertigo ovata, showing variations in teeth (see next page).
Vertigo ovata Say.

Range. — Eastern United States from Maine to Texas, and northward. Mexico?

Vertigo arctica Wallenberg.

Range. — Lapland and northern Scandinavia, the mountains of Germany and the Tyrol; eastern Siberia at Emma Harbor, Plover Bay; Port Clarence on the American side of Bering Strait (Vega Expd.).

*Vertigo krauseana* Reinhardt.

Range. — Chukchi Peninsula of eastern Siberia; at Poot, St. Lawrence Bay, and Ratmanof Harbor. Alaska, at Chilkat Inlet!

Specimens of this species labeled Chilkat Inlet were received from Dr. Krause; but in the publications on this form only the Siberian habitats are given. I suspect some error has occurred in labeling, though it is entirely possible that the species may occur in Arctic America.

*Vertigo (Vertilla) milium* Gould.

Range.—New England to Texas and Florida, west to Minnesota. Ontario, Canada.

This minute species doubtless exists on the northern side of the boundary, though not yet reported there.

*Vertigo (Isthmia) pygmaea* Draparnaud.

_Pupa pygmaea_ DRAPARNAUD, Tableau, p. 57, 1801; Hist. Moll. Terr., p. 60, pl. iii, figs. 20–21, 1805.

Vertigo callosa STERKI, not Reuss, and _P. superioris_ PILSBRY, _fide_ PILSBRY, i. c.

Range.—Europe, Asia Minor, the Caucasus; America, in the northeastern States and the Lake Superior region.

Family **ACHATINIDÆ**.

Genus **Cochlicopa** (Férussac) Risso.

**Cochlicopa lubrica** Müller.

_Zua lubrica_ LEACH, Syn. Moll. Gt. Brit., p. 114, 1852; Gray’s Turton’s Man., p. 188, pl. vi, fig. 65; 1840.

_Bulimus lubricoides_ STIMPSON, Shells of New England, p. 54, 1851.

_Zua lubricoides_ MORSE, Jour. Portland Soc. Nat. Hist., i, p. 30, figs. 79, 81, 84; pl. x, fig. 82, 1864; Am. Nat., i, p. 607, fig. 49, 1868.

_Ferussacia subcylindrica_ auct. non L.

Range.—Europe, North Africa and Asia Minor: Siberia; Kamchatka; most of North America.

Lake Superior region; Red River of the North, Lake of the Woods and Turtle Mountain, Manitoba; Moose Factory! English River, Keewatin; Laggan and Red Deer in Alberta; Nanaimo and Victoria, British Columbia; Point Barrow! and Yukon valley, Alaska; Avacha Bay! Kamchatka.

This well known shell is one of the most emphatically circumpolar species in existence, and considering its immense geographical and climatic range its resistance to the factors which make for variation is very remarkable.

Family **CIRCINARIIDÆ**.

Genus **Circinaria** Beck.

This is _Macrocyclis_ or _Selenites_ of recent literature, not of Beck or Hope.
Circinaria vancouverensis Lea.

_Helix vancouverensis_ Lea, Trans. Am. Phil. Soc., vi, p. 87, pl. xxiii, fig. 72, 1839.

_Macrocyclus vancouverensis_ Tryon, Am. Journ. Conch., ii, p. 245, pl. iii, fig. 6, 1866. — Binney, Land and Fw. Sh. N. Am., i, p. 54, figs. 90-93, 1869.

_Circinaria vancouverensis_ PILSBRY, Class. Cat. Am. Landsh., p. 24, 1898.

**Range.** — In the moist and wooded region of northern California and northward to the Alexander Archipelago, Alaska, between the Cascade Range and the sea.

Vancouver Island! Quatsino Sound, Broughton Strait, Malcolm Island, Johnstone Strait, Harbledown and Pender Islands, Skidegate, Graham Island, and Cumshewa Inlet, Moresby Island, Queen Charlotte Islands! Union Bay! and Comox! British Columbia. In Alaska at Annette Island! Killisnoo, Sitka! Lynn Canal, throughout the Alexander Archipelago, and northward along the mainland shore to Lituya Bay.

The typical form of this species is readily recognizable by its ample whorls, the last nearly smooth, its large size and greenish yellow color. It grades, however imperceptibly, into the smaller and more strongly sculptured _C. sportella_ Gould, from which cause a large number of varieties have arisen and been named. In the moist mountainous region of the Columbia drainage some of these forms penetrate to the eastward nearly to the headwaters of this river in western Montana. They are all depauperate, however, compared with the typical well nourished forms of the coast. These animals are carnivorous, voracious and cannibalistic. It is unsafe to keep them living in the same receptacle with other living snails, as they will rapidly destroy and consume the soft parts.

A fine sinistral specimen was collected at Sitka.

A variety of a dark chocolate brown color, otherwise like the ordinary form, was found rather commonly at Sitka. For this the varietal name _chocolata_ would seem appropriate.

Specimens of this species were received with a label indicating that they had been collected on the Alaska Peninsula opposite Kadiak Island, but, knowing the habits of this animal, I regard this as an error of labelling. The collector having died, I was unable to untangle the confusion, but I have never found it far distant from the wooded region where _Ariolimax_ and _Polygyra columbiana_ occur, upon which it chiefly feeds in Alaska. It does not occur, so far as I was able to discover, on the shores of Cook Inlet, where there are suitable forests,
and I do not believe it occurs on the treeless grassy slopes of the peninsula. I suspect that the wide-stretching glacial area to the north and west of Yakutat Bay, puts an impassable barrier to its northwestern migration, and that it may not exist in the forests beyond that area.

This is the largest shell-bearing Pulmonate known to live in Alaska, but is surpassed by the great slug *Ariolimax*, which often extends to the length while preserving the diameter of a large cigar.

**Circinaria** variety *sportella* Gould.

This is a variety of *C. vancouverensis* of smaller size, and intensified sculpture, both spiral and incremental. Intermediate forms, to which several names have been applied, connect it with the typical form. It accompanies the latter throughout its range, but occurs in some localities which do not support the larger form. Among northern localities it has been collected at Saanich, Comox! Union Bay! Salt Springs Island and Chilliwak Lake, British Columbia; at Annette Island! (with variety *hybrida* Ancey) and Lituya Bay! Alaska.

**Circinaria** variety *hybrida* Ancey, 1888.

This form is reported from Vernon and Comox, British Columbia, and Annette Island, Alaska.

**Circinaria hemphilli** Binney and *C. voyana* Newcomb, have not been authentically reported north of the boundary, though it is said both of them have been collected in the Puget Sound region.

**Family ZONITIDÆ.**

**Genus Vitrina** Draparnaud.

*Limacina* Hartmann, Neue Alpina, i, p. 206, 1821; Sturm's Deutschl. Fauna, abth. vi, heft v, pp. 41, 54, 1821; not of Cuvier, 1817.

*Semilimax* Férussac père, Der Naturforscher (Halle), pt. 28, 1802; *fide* Férussac fils, loc. cit., 1821.

Pagenst GISTEL, Naturg. Thier., p. 168, 1848 (new name for Vitrina Drap.).

Helicolimax KOBELT, Cat. der Europ. Faun. leb. Binnenconch., p. 4, 1871, (Sect. of Vitrina, s.s.).

The shell in this group and its allies is reduced to very simple terms and the differences between species appear trifling. But there appears to be quite a wide range of character in the soft parts, from whence it follows that several sections can be recognized in the genus as restricted, while some species, formerly regarded as belonging to Vitrina, are now scattered in widely separated genera.

The true Vitrina seems confined to the northern hemisphere. The following sections are recognized:

Vitrina Drap. s. s. 1801. Type V. pellucida Müller. Helicolimax Féru, 1801, is identical, and Semilimax Stabile hardly separable.

Oligolimax FISCHER. Type V. pauluccia Fischer.

Phenacolimax Stabile, 1859. Type V. major Fér.

Gallandia Bourguignat, Aug., 1880. Type V. coneidea von Martens. Trochovitrina Schacko, Oct., 1880, is synonymous.

The North American and Greenland species are true Vitrina, the other forms belong to the Old World only.

The New World groups Vitrinozonites Binney and Velifera Binney may be regarded as of generic rank, and are extra limital to the region now under discussion.

Vitrina angelica BECK, Index, p. 1, 1837; name only.—MÖLLER, Index, p. 4, 1842.—MÖRCH, Am. Journ. Conch., iv, p. 27, pl. iii, figs. 1, 4, 1868.—MÖRCH, in Rink's Danish Greenland, p. 436, 1877.

Helix pellucida FABRICIUS, Fauna Grön., p. 369, 1780, not of Müller, 1774.
Range. — Greenland.

This species is more like the *V. beryllina* of Europe than the American species. The latest data given by Posselt indicate that it is not found in Iceland. Binney has given an enlarged illustration of this species (fig. 25) in his Land and Fresh Water Shells of North America, 1, p. 28.

**Vitrina limpida** Gould.

*Vitrina pellucida* DE Kay, Zool. N. Y. Moll., p. 25, pl. III, fig. 42, 1843; not of Müller, 1774.

Range. — Central New York and northward, from New Brunswick to Alberta and Hudson Bay.

Pittsburgh, Pennsylvania. Manitoba at Carberry and Lake of the Woods; Red Deer and Laggan in Alberta; Moose Factory! James Bay; Norway House, in damp woods.

This species has been reported from the Rocky Mountain region by Ingersoll, but I regard his specimens so identified as varieties of *V. alaskana*.

**Vitrina alaskana** Dall, nom. nov.

Range. — New Mexico, Utah, Colorado, central California, all at considerable altitudes, and northward.

Nanaimo, Vancouver Island, B. C.; Muir Inlet, Alaska! St. Paul, Kadiak Island! Popof and Unga Islands, of the Shumagin group! Akutan! Unalga! Rooluk! and Unalaska! of the Aleutian chain; St. Paul! and St. George Islands, Bering Sea, Alaska, in tall grass of bluff fifty feet above the sea!

This species has been referred to as *pellucida*, *limpida* and *exilis*, and when fully grown under favorable conditions the shell may reach 10 mm. in major diameter, though most of the specimens as collected are considerably smaller. The shell is translucent, with a marked greenish tinge, and not over three whorls. It is flatter than *limpida*,
larger, and of a different tint, and the size of the whorls increases more rapidly. It is less flat and much larger than \( V. \ exilis \), which is also of a different hue.

It is the most common land shell on most of the islands of Bering Sea and on the continent near the sea, where it usually occurs, but as we move southward we find it occurring at continually greater elevations and entirely absent from the warm dry plains and valleys. It attains from 7,500 to 10,800 feet elevation in the Sierra and Rocky Mountains.

*Vitrina exilis* Morelet.

**Range.** — Northeastern Asia and adjacent islands, from Japan northeastward.

Kamchatka, at Petropavlovsk! Bering Id. (Vega Expd.).

This is a small species, of a whitish or translucent glassy hue; smaller and with a more elevated spire than its American representative *V. alaskana*. According to Binney *V. exilis* has the jaw and radula as usual in the genus, the transverse rows of teeth numbering 37 \( \cdot 1 \cdot 37 \); with seven perfect laterals.

I have seen no specimens from east of the Commander Islands; the shells thus identified are probably all *V. alaskana*.

**Genus Vitrea** Fitzinger.

*Vitrea radiatula* Alder.

*Helix radiatula* ALDER, Cat. Test. Newcastle upon Tyne, p. 12, No. 50, 1830.—GRAY, in Turton's Man., p. 173, pl. XII, fig. 137, 1840.

*Helix electrina* GOULD, Inv. Mass., p. 183, fig. 111, 1841.

*Hyalina viridula* BINNEY, Land and Fw. Sh. N. Am., I, p. 34, figs. 41-43, 1869; not of Menke?

*Hyalina pellucida* LEHNERT, Science Record, II, p. 172, June 16, 1884.

**Range.** — Holarctic. Northern Europe, Asia and America.

The species as described by Ström is unrecognizable and his name should be rejected. There is some doubt as to whether the *Z. viridula* of Menke is identical with the present species or not.

**Vitrea nitidula** Draparnaud.

*Zonites nitidulus* GRAY, in Turton, Man., p. 172, pl. xii, fig. 136, 1840.

*Range.* — Europe, northern and middle; Italy.

Fort Resolution! Great Slave Lake (Kennicott).

The identification and locality are indubitable.

**Vitrea binneyana** Morse.

*Hyalina binneyana* Morse, Journ. Portland Soc. Nat. Hist., i, p. 13, figs. 25, 26, pl. ii, fig. 9, pl. iv, fig. 31, 1864. — BINNEY, Land and Fw. Sh. N. Am., i, p. 39, figs. 56-8, 1869.

*Hyalina binneyi* BINNEY, Land and Fw. Sh. N. Am., i, p. 39, footnote.

*Vitrea binneyana* PILSBRY, Class. Cat., p. 26, 1898.

*Range.* — Quebec and Maine to northern Michigan and British Columbia.

Brandon, Manitoba; Nanaimo, B. C.

**Vitrea indentata** Say.

*Hyalina indentata* MORSE, Journ. Portland Soc. Nat. Hist., i, p. 12, fig. 21; pl. ii, fig. 11, pl. v, fig. 22, 1864. — BINNEY, Land and Fw. Sh. N. Am., i, p. 35, figs. 44-46, 1869.

*Range.* — Mexico to Manitoba, United States and Canada, eastward from the Rocky Mountains. Pine Creek, Manitoba.

**Genus Euconulus** Reinhardt.

*Helix* (sp.) MÜLLER, Gmelin, Montagu, Draparnaud, et al., 1774-1820.

*Teba* (sp.) LEACH, Proofsheets, 1820, fide Rössmässler Icon., ii, p. 38, 1838.

*Petasia* (sp.) BECK, Index, p. 21, 1837.

*Zonites* (sp.) MOQUIN TANDON, Moll. de France, p. 68, 1855.

This genus has had a number of names applied to it, among which one is proposed by Westerlund as taken from Da Costa (1778) but, as indicated by Sherborne in the Index Animalium, Da Costa merely quoted part of a polynomial phrase (\textit{Trochilus terrestris mortoni}) in his synonymy, from Morton's Northamptonshire (London, 1712), and did not use the word \textit{Trochilus} in a generic sense. Moreover, if he had, \textit{Trochilus} had previously been used by Linné for a genus of birds. There seems at present no reason to doubt that the first valid name for the genus is \textit{Euconulus} Reinhardt, while the typical species, as will be evident from the following synonymy, is \textit{E. trochiformis} (Montagu).

**Euconulus trochiformis** (Montagu).

\textit{Trochus terrestris} (LISTER) DA COSTA, Brit. Conch., p. 35, 1778; not of Pennant, 1767.

\textit{Helix nitidula} VON ALTEN, Syst. abh. Erd. u. Fluss-Conch., p. 53, pl. iv, fig. 8, 1812.

\textit{Helix mandralisci} BIVONA, Nuovo Moll. Palermo, p. 16, pl. 1, fig. 6, 1839.

\textit{Helix fulva} var. mortoni JEFFREYS, Linn. Trans., vi, p. 332, 1830.

\textit{Conulus fulvus} FITZINGER, Syst. Verz., p. 94, 1833.

\textit{Helix (Petasia) trochiformis} BECK, Index, p. 21, 1837.

\textit{Helix} (\textit{Conulus}) \textit{fulva} ALBERS, Heliceen, p. 73, 1859.

\textit{Hyalinia (Conulus) fulvo} VON MARTENS’ ALBERS, p. 73, 1860.

Hyalina (Conulus) fulva BINNEY, Land and Freshw. Sh. of N. Am. part i, p. 46, fig. 73, 1869.

Trochulus trochiformis WESTERLUND, Fauna Pal. Reg., III

Conulus chersinus MORSE, Journ. Portland Soc. N. Hist., i, p. 19, figs. 44, 46, pl. ii, fig. 4, pl. vii, fig. 45, 1864, not Helix chersina Say, 1821.
Conulus fulvus (MÜLLER), and var. alaskensis PILSBRY, Nautilus, XII, No. 10, pp. 115-6, 1899.

Euconulus fulvus PILSBRY, Nautilus, xiv, Nov., 1900, p. 81.

Variety fabricii (Beck).

Helix nitida FABRICIUS, Fauna Grönl., p. 389, 1780, not of Müller.

Range. — Holarctic, and widely distributed southward.

Canada; Manitoba at Carberry, Pine Creek, Pembina, and Lake of the Woods; in Alberta at Laggan, Red Deer, Olds and McLeod; English River, Kee-watin; California! Oregon! Washington! Victoria, Vancouver Island! Sitka, Alaska! Unalaska! Bering Island, Bering Sea! Petropavlovsk, Kamchatka! Pooten, Konyam and St. Lawrence Bays, eastern Siberia.

Variety fabricii Möller. Greenland! Ungava! Labrador.

Variety alaskensis Pilbry. Yukon drainage, Lake Lindeman to Point Romanof and St. Michael, Alaska; Dyea valley, Southeastern Alaska!

This familiar little shell has had various vicissitudes in nomenclature. The name fulva Müller, by which it is best known, was based, according to Beck, who was custodian of Müller's types, upon Helix bidentata Gmelin, while a shell which Müller supposed to be the young, but did not figure or fully describe, was supposed by some of the early naturalists to be our species. Another unfigured species, Helix trochulus Müller, was thought by Dillwyn to be identical with our fulva, but the measurements forbid the identification, and Pfeiffer came to the conclusion that H. trochulus is identical with the young tip of Bulimus obscurus. Fabricius supposed our shell to be identical with Helix

Fig. 28. Euconulus trochiformis (magnified).

Fig. 29. Euconulus trochiformis var. fabricii, i (Greenland).
*hammonis* Ström (1765), but Ström’s figure is widely umbilicated and so rude as to be practically unidentifiable.

The first specific name which unmistakably applies to our shell, and to it alone, is the *trochiformis* of Montagu, which it seems advisable to adopt.

Under the name *fulva* several distinct though very closely allied forms have been generally included. Reinhardt, Bourguignat and lastly Pilsbry have thrown additional light on this subject, and a number of species or marked varieties are now recognized. The *Helix chersina* of Say is a southern form, while the *H. egna* of Say is generally admitted to be a synonym of the *trochiformis*.

The *Euconulus fabricii* of Greenland seems to be merely a case of an offshoot which by isolation has been enabled to assume distinctive characters, which have hardly reached a greater than varietal rank.

Genus *Zonitoides* Lehmann.

**Zonitoides nitidus** Müller.

*Helix lucida* Draparnaud, Hist. Moll. de France, p. 103, 1805; not of the Tableau, 1801.

*Zonitoides nitidus* Pilsbry, Class. Cat., p. 27, 1898.

**Range.**— Holarctic. Europe, northern United States, British America, Alaska, Japan.

Red River drift, Manitoba; Peace River, Athabaska; Fort Resolution, Great Slave Lake; Seattle, Wash. ! Klukwan, Alaska (Krause).

This species has been found so widely spread that it cannot reasonably longer be regarded as merely a European emigrant.

**Zonitoides arboreus** Say.

*Helix arborea* Say, Nicholson’s Encyl., 1st Am. edition, pl. IV, fig. 4, 1817.

**Range.**— North America generally and Japan.

Labrador; Ontario; English River! Keewatin and Moose Factory; Carberry and Lake of the Woods, Manitoba; Laggan and Red Deer, in Alberta; Great Slave Lake! Oregon, at Weston! Vancouver Island at Victoria! Departure Bay! Nanaimo! Comox! Union Bay! etc.; in Alaska at Unalaska! Petropavlovsk, Kamchatka! Japan (Hirase).
Zonitoides randolphi Pilsbry.

Zonitoides randolphi Pilsbry, Nautilus, xii, p. 87, 1898. — RANDOLPH, op. cit., p. 110, 1899.

Range. — Lake Lindeman, headwaters of the Yukon, British America.

I have not seen this species, which is less than 5 mm. in diameter. It has not been figured.

Zonitoides minusculus Binney.

Pseudohyalina minuscula MORSE, Journ. Portland Soc. N. Hist., i, p. 16, fig. 34, pl. vii, fig. 35, 1864.

Range. — North America generally.

Red River of the North, Manitoba; Victoria and Departure Bay! Vancouver Island; Berg Bay, Muir Inlet! Alaska; Coal Harbor, Unga Island, Shumagins! Rooluk Island! near Unalga, Aleutians, Alaska.

Zonitoides milium Morse.

Striatura milium MORSE, Journ. Portland Soc. Nat. Hist., i, p. 18, figs. 41, 42, pl. vii, fig. 43, 1864.

The report of this species from Vancouver Island was probably based on the following form. *Z. minusculus* has also been wrongly identified as *Z. milium*.

Zonitoides pugetensis Dall.

Patulastra ? (Punctum ?) pugetensis DALL, Nautilus, viii, No. 11, p. 130, Mar., 1895.

Zonitoides pugetensis PILSBRY, Nautilus, ix, p. 18, 1895.

Range. — Puget Sound region, Oregon, California. Seattle, Wash. ! Nanaimo, Vancouver Island.

Genus Gastrodonta Albers.

*Gastrodonta gularis* Say?

Helix gularis J. DE C. SOWERBY, in Richardson, Fauna Bor. Am., iii, p. 315, 1836 (nude name).

Range. — Lake Superior, Winnipeg, and Saskatchewan River (Sowerby).
This name is doubtless one given by Sowerby to some unknown shell, as it is as certain as almost anything can be, that *Helix gularis* Say was never collected in the region referred to.

Genus **Pristiloma** Ancey.

**Pristiloma lansingi** Bland.

*Pristiloma lansingi* PILSBRY, Class. Cat., p. 29, 1898.

Astoria, Oregon! Seattle, Wash.! common at Victoria! and Nanaimo! Vancouver Island.

**Pristiloma stearnsii** Bland.

**Range.**—Columbia River to Dyea, Alaska.

**Pristiloma taylori** PILSBRY.

**Range.**—Oregon, Washington and British Columbia at Nanaimo, Vancouver Island.

*Pristiloma pilsbryi* Vanatta.

**Range.**—Portland, Oregon.

*Pristiloma idahoense* PILSBRY.

**Range.**—Idaho, in Washington and Boise counties at Weiser Canyon and Big Payette Lake.

This and the preceding species will probably be found within our area when it is thoroughly explored.
Pristiloma? arctica Lehnert.

Hyalina arctica LEHNERT, Science Record, II, p. 172, June 16, 1884.

Range. — Yakutat Bay, Alaska, to Point Barrow.

Point Barrow, Lat. 71° 25' N. ! Unalaska ! Coal Harbor, Unga Island, Shumagins ! Orca, Prince William Sound ! and Yakutat Bay, Alaska !

This may prove to be a depressed Euconulus when the animal is anatomically examined.

The species was formerly confused with P. stearnsii. It occurs in the moss of the tundra near Point Barrow, where at most it can have but three months of activity out of the whole year.

Family LIMACIDÆ.

Genus Agriolimax Mörch.

Agriolimax agrestis Linné.

Range. — Both coasts of America, introduced from Europe.

Victoria, B. C. ! Manitoba ; Ungava !

Agriolimax hyperboreus Westerlund.

Limax hyperboreus WESTERLUND, Land och Sötv. Moll. Sibiriens, p. 21, 1876.

Range. — The Arctic and boreal regions of both hemispheres.

Bering Id. ! Kamchatka ! Chukchi Peninsula! Alaska at Norton Sound ! Nushagak ! Unalaska ! Coal Harbor, Shumagins ! St. Paul Island, Bering Sea ! Kadiak Island ! Sitka ! and Cape Fox ! In Vancouver Island at Comox ; Seattle, Wash. ; Alberta at Laggan, altitude 5,200 feet ; Manitoba ; Ungava, Labrador !

This little black slug is the prevalent and almost the only animal of its kind in the higher latitudes of North America. It has been referred
to \textit{A. campestris} as a variety by some authors, but it is at least the only form of \textit{campestris} known in the north and seems distinct enough to be recognized as a species.

**Agriolimax berendti** Streb.  
\textit{Limax berendti} STREBEL and PFEFFER, Mex. 1. u. süßw. Conch., IV, p. 22, pl. IX, figs. 10, 12; pl. XV, fig. 3, 1880.  

\textit{Range.} — Guatemala to British Columbia.

**Genus \textit{Amalia}** Moquin Tandon.  
\* \textit{Amalia hewstoni} Cooper.  
\textit{Amalia hewstoni} PILSBRY, Class. Cat., p. 29, 1898.  

\textit{Range.} — San Diego to Seattle. San Francisco, Calif.!

This form may perhaps be an evolution from imported specimens of the European \textit{A. gagates}. It probably extends into British Columbia.

**Family \textit{ARIONIDÆ}.**  
**Genus \textit{Prophysaon}** W. G. Binney.  
\textit{Prophysaon andersoni} Cooper.  
\textit{Prophysaon andersoni} var. \textit{marmoratum} and \textit{sussium} COCKERELL, The Conchologist, II, pp. 72, 118.  
\textit{Prophysaon andersoni} var. \textit{pallidum} COCKERELL, Nautilus, V, p. 31, July, 1891.  

\textit{Range.} — San Francisco north to Alaska and eastward to Idaho. Variety \textit{pallidum} Cockerell, Vancouver Island! British Columbia; Cape Fox, Alaska!  

Type \textit{(andersoni)} Victoria and Nanaimo, British Columbia.  
\textbf{Var.} \textit{pacificum} Cockerell, Victoria, B. C.!

I have followed Dr. Pilbsry's arrangement of the varying forms of this remarkable self-amputating slug.
*Prophysaon foliolatum* Gould.

*Phenacarion foliolatus* Cockrell, Nautilus, iii, p. 127, Mar., 1890.

*Phenacarion hemphilli* W. G. Binney, 3d Suppl. Terr. Moll., v, p. 208, pl. viii, fig. c, ix, fig. h; 4th Suppl., p. 183; not *Prophysaon hemphilli* Bland and Binney.

*Prophysaon foliolatum* (Gould) Pilsbry, Proc. Acad. Nat. Sci. Phila., for 1898, p. 248, pl. x, figs. 15, 16, 17; pl. xi, fig. 32; pl. xiii, figs. 55, 56, 57, 58; pl. xiv, fig. 70; pl. xv, fig. 80; pl. xvi, figs. 90, 98.

Range.—Puget Sound region.

*Prophysaon humile* Cockrell.

*Prophysaon fasciatum* Cockrell, in Binney, 3d Suppl. Terr. Moll., v, p. 209, pl. vii, fig. a, 1890.—Pilsbry, op. cit., p. 251, pl. x, figs. 23-27; pl. xi, fig. 34; pl. xii, figs. 37-40; pl. xvi, figs. 91, 94-96.

*Prophysaon fasciatum var. obscurum* Cockrell, The Conchologist, ii, p. 119, Mar. 1893.

Range.—Northern Idaho to Puget Sound and northward to Alaska.

*P. humile* Loring, Alaska! Seattle!

*P. fasciatum* Old Mission, Idaho; Chehalis and Seattle, Wash.

*Prophysaon coruleum* Cockrell.

*P. coruleum var. dubium* Cockrell, loc. cit., 1890.

Range.—Portland, Oregon; Seattle and Olympia, Wash.

Genus *Ariolimax* Möhrch.

*Ariolimax columbianus* Gould.

*Limax columbianus* Gould, Terr. Moll., ii, p. 43, pl. lxvi, fig. 1, 1851; Moll. U. S. Expl. Expd., p. 3, fig. 1, a, b, 1852.

Range.—Santa Barbara, northward to Sitka, Victoria, and Nanaimo. Malcolm Island and Broughton Strait, British Columbia; SE. Alaska (to Cross Sound?) Klawak, Prince of Wales Archipelago! Sitka, Alaska! and probably north to Cross Sound and Icy Strait, or even Lituya Bay.
This is the common slug of British Columbia and Alaska, found in damp places in the wooded region. It varies from dark maculate to yellowish olive, and when full grown may reach a length of eight or nine inches, when fully extended. It is very fond of the leaves of the Alaskan skunk cabbage, a taste shared by bears and the Alaskan deer. It produces a profuse and most tenacious slime. When the Indians wish to catch the ruby-throat humming bird they gather two or three of these slugs and whip them with small bare twigs. Under this treatment slime is given off in large quantity and adheres to the twigs, which are afterward placed among the flowers visited by the hummers. If they alight on one of the twigs they cannot escape from the adhesiveness of this singular birdlime. It is said one of the ancient chiefs had a cape entirely covered with the resplendent plumage of the male ruby-throat, and which was regarded as incredibly valuable. The black spotted form seems to have been named maculatus, by Cockerell, and the yellow mutation stramineus, by Hemphill, but they occur indiscriminately in Alaska and are probably only individual color-mutations.

* Ariolimax steindachneri Babor.

Range. — Puget Sound.
I am unable to state whether this is distinct or one of the mutations of A. columbianus.

Genus Hemphillia Bland and Binney.

* Hemphillia glandulosa B. and B.

Range. — Astoria, Oregon, and Puget Sound region.

* Hemphillia camelus Pilsbry and Vanatta.
Hemphillia camelus PILSBRY and VANATTA, Nautilus, xi, p. 44, Aug., 1897; Proc. Acad. Nat. Sci. Phila., for 1898, p. 234, pl. ix, figs. 3, 4; pl. xii, figs. 41, 42; pl. xvi, fig. 85.
Range. — Northern Idaho, at Old Mission. Like other species of northern Idaho this probably extends across the parallel into British America.

Family ENDODONTIDÆ.

Genus Pyramidula Fitzinger.

Subgenus Patula Held.

Pyramidula solitaria Say.

Pyramidula solitaria limitaris Pilsbry, Class. Cat. Am. Landsh., p. 31, 1898.

Patula solitaria var. occidentalis von Martens, fide Pilsbry, l. c., p. 31, 1898.

Range. — Arkansas north to Ohio, west to eastern Oregon, and northward in Alberta.

Var. limitaris, Waterton Lake, Rocky Mts. in Alberta; northern Idaho.

Var. occidentalis, Dalles of the Columbia near Fort Vancouver; Cœur d'Alene Mts., Idaho.

*Pyramidula alternata* Say.

Anguispira alternata Morse, Journ. Portland Soc. N. Hist., I, p. 11, fig. 15, pl. IV, fig. 16, 1864.

Range. — Eastern North America as far north as Nova Scotia, Lower Canada, and the international boundary.

Lake of the Woods! (Kenneicott); Canso, Nova Scotia (*fide* Binney).

Binney (*op. cit.*., pp. 74, 76) gives the northeastern range of this species as Labrador, but Canso, where his specimens were obtained, is
in Nova Scotia, not Labrador. I have no authentic record of this species north of Lake of the Woods.

Subgenus *Gonyodiscus* Fitzinger.

**Pyramidula striatella** Anthony.

*Patula striatella* Binney, Man. Am. Land Shells, p. 69, figs. 28, 29, 1885.

**Range.**—Kansas northward to Great Slave Lake and from New England to the Sierra Nevada, and south to Arizona. Woods of the Winnipeg basin, Turtle Mt., Lake of the Woods! English River! Manitoba; Moose Factory! James Bay; Great Slave Lake at Fort Resolution! in Alberta at Laggan, Red Deer, Olds, and McLeod, west to the Selkirk Range.

It is difficult to distinguish immature specimens of this species from *P. cronkhlitei* Newc., but when full grown perfect specimens are compared it is seen that *striatella* is a smaller shell with a proportionately larger umbilicus, it is of a richer brown color, more regularly and elegantly ribbed and more polished or glistening on the surface. The animal of *striatella* shows no red maculations through the translucent shell when living, such as are seen in *P. ruderata*.

**Pyramidula cronkhlitei** Newcomb.

*Pyramidula striatella cronkhlitei* Pilsbry, Class. Cat. Am. Landsh., p. 32, 1898.

**Range.**—Nevada and California in the wooded mountain region to 6,000 feet; Klamath Lake and valley, Oregon, and northward.

British Columbia at Nanaimo; Lake Lindeman, Yukon Territory; in Alaska at Sitka! Chilkat Inlet! and valley; Chilkoot Inlet! and valley! shores of Yakutat Bay! English Bay (Merriam)!, and St. Paul, Kadiak Island! Popof and Unga Islands! Shumagins; Chika Rocks! and Akutan Island! Akutan Pass; Unalaska (Dall, Elliott, Kincaid, Turner)!

Mr. Binney observes that this species is larger, of a lighter color, is more coarsely (and I may add more irregularly) striated than *P. striatella*. It also has when full grown a larger shell and relatively smaller and deeper umbilicus. I am obliged to confess that I am not able to distinguish shells long dead from those of *P. ruderata*, which
replaces this species on Bering Island and in Kamchatka. But when the animals are living *P. ruderata* shows through the translucent shell deep red or red-brown radiating maculations, which are situated on the mantle. After the shells have been dead some time this maculation disappears. Now the living *P. cronkhitei* do not show any such color-markings. The presence of the latter led Morelet to name an immature *ruderata*, *Helix floccata*. The shell figured by von Martens in the Conchologische Mittheilungen under the name of *floccata* does not agree with Morelet's original diagnosis, and was not found by me during much energetic collecting at his locality, Petropavlovsk, Kamchatka, in 1865. If, as stated by von Martens, it really comes from the original lot collected by Morelet it is evident that his diagnosis (which calls for a shell with an angular periphery like young *ruderata*) was founded on a mixture, of which young *ruderata* probably formed a part. But I am inclined to believe that von Martens was misled in regarding the shell he figured to be a native of Kamchatka.

*Pyramidula pauper* Gould was described from the same locality as Morelet's *floccata*, and is undoubtedly the same as the shell I have called *ruderata*, following Morelet, Middendorff and others. But the *P. cronkhitei* from Unalaska and other places in Alaska which has been called *pauper* by Dr. Cooper and others, is our American shell. Mr. Binney thought it different from *P. cronkhitei*, but after much study and consideration I cannot confirm this opinion.

Subgenus *Planogyra* Morse.

*Pyramidula asteriscus* Morse.

*Planogyra asteriscus* Morse, Journ. Portland Soc. Nat. Hist., i, p. 24, figs. 51, 52; pl. ii, fig. 5; pl. viii, fig. 53, 1864.

*Pyramidula (Planogyra) asteriscus* Pilsbry, Class. Cat. Am. Landsh., p. 33, 1898.

Range. — Maine; Provinces of Quebec and Ontario, Canada; Vancouver Island? Tacoma, Wash.?

This species has been reported from British Columbia and Washington, but it seems the identification is somewhat doubtful, and the shells were probably *Punctum clappi* Pilsbry.

Genus *Oreohelix* Pilsbry.

*Oreohelix strigosa* Gould.

**Oreohelix strigosa** PILSBRY, Nautilus, xvii, No. 11, p. 131, footnote, 1904.

**Range.**—Type at Spokane, Wash., also in the Rocky Mountain region from northern Mexico to and somewhat beyond the 49th parallel westward from the Lake of the Woods.

**Var. cooperi**, Lake of the Woods, and westward to the Rockies near the 49th parallel.

**Var. stantoni** Dall (1905). Thirty-three miles southeast of Medicine Hat, Assiniboia, near top of Cypress Hills, altitude 4,700 feet; latitude about 49° 30', west longitude 110° 10'.

The variety *stantoni* is dwarfed, measuring in maximum diameter 10.0, minimum 8.5, and height 8.0 mm., with about five whorls, a peripheral brown band with a narrower one above and sometimes others on the base, the remainder ashy, rudely incrementally striate, with rounded periphery and deep narrow (1 mm.) umbilicus. It is very similar to some varieties of the European *H. virgata* Da Costa. Eight specimens were collected by Dr. T. W. Stanton in 1903.

A large number of names, varietal and other, have been given to the mutations of this species, which barely enters the region covered by this memoir, at its southern border near the Rocky Mountains. The group is viviparous, and the young attain a large size before extrusion.

**Genus Helicodiscus** Morse.

**Helicodiscus lineatus** Say.

**Helicodiscus lineatus** Morse, Journ. Portland Soc. Nat. Hist., 1, p. 25, figs. 61, 62, pl. 11, fig. 3; pl. VII, fig. 63, 1864.—BINNEY, Man. Am. Landsh., p. 75, figs. 34–37 A, 1885.

**Range.**—New Mexico to Manitoba, New England to California. Reported as rare in Manitoba by Hanham.

**Fig. 36. Helicodiscus lineatus**, shell and animal (magnified).
Genus *Punctum* Morse.

**Punctum pygmaeum** Draparnaud.

*Helix pygmaea* Draparnaud, Hist. Moll., p 114, pl. viii, figs. 8, 9, 10, 1805.

**Punctum minutissimum** Morse, Journ. Portland Soc. Nat. Hist., i, p. 27, figs. 69, 70, pl. viii, fig. 71, 1864.

*Microphysa pygmea* Binney, Man. Am. Landsh., p. 71, figs. 31-33, 1885.

*Punctum pygniceum* PILSBRY, Class. Cat. Am. Landsh., p. 33, 1898.

Range.—United States generally; Quebec; Manitoba; Victoria, Vancouver Island. Europe.

*Punctum randolphi* Dall.

*Pyramidula? randolphi* Dall, Nautilus, viii, p. 130, Mar., 1895.

**Punctum randolphi** PILSBRY, Nautilus, ix, p. 18, June, 1895.—Dall, Proc. U. S. Nat. Mus., xxiv, p. 500, pl. xxvii, figs. 7, 8, 9, 1902.

Range.—Seattle, Wash.

Probably exists throughout the Puget Sound region and adjacent British Columbia.

**Punctum clappi** PILSBRY.

**Punctum clappi** PILSBRY, Nautilus, xi, p. 133, Apr., 1898; Class. Cat. Am. Landsh., p. 33, 1898.

Range.—Oregon, Washington, Vancouver Island.

Salem, Wash.; Tacoma, Wash.; Seattle, Wash.; Nanaimo and Comox, Vancouver Island.

This is probably the shell which has been reported as *P. asteriscus* Morse, from Vancouver Island and Tacoma. It has not been figured.

**Punctum conspectum** Bland.

**Punctum conspectum** PILSBRY, Nautilus, xi, p. 133, Apr., 1898; Class. Cat. Am. Landsh., p. 32, 1898.

Range.—West America from middle California northward, and east to the west slope of the Rocky Mountains. Kamchatka.

California! Oregon; Washington; Puget Sound region generally; Victoria, British Columbia! Departure Bay, Vancouver Island! Sitka! Chilkoot Inlet and valley; Chilkat Inlet and valley; Coal Harbor! Unga Island, Shumagins; Unalaska! Alaska. Petropavlovsk! Kamchatka (Dall).
The most common of the minute species in Alaska; often found in numbers under bits of cast-off leather and chips near the tops of beaches. The Kamchatkan specimens are beyond suspicion.

Genus *Sphyradium* Charpentier.

*Sphyradium edentulum* Draparnaud.

*Pupa columella* 'Benson,' var. *gredleri* Clessin, from Alaska, is probably *S. edentulum*.

**Range.**—Northern Europe, Asia and America.

![Image](image-url)

**Fig. 37. Sphyradium edentulum** (magnified).

This species has a wide distribution and considerable synonymy.

**Unidentified Species.**

The following *Helicina* are *incerta sedis*.

"Lake Superior, Winnipeg and Saskatchewan River."

"Lake Superior, Winnipeg, and Saskatchewan River."

This species, supposed to have been collected by Capt. Belcher, during his voyage to the Northwest Coast of America, has not been recognized from that quarter since; and probably, like many other
species brought home by Belcher from time to time, had got wrongly labelled.

Family SUCCINEIDÆ.

Genus Succinea Draparnaud.

Amphibulina Hartmann, in Sturm, Fauna Deutschl., vi, pp. 42, 55, 1821; 1st sp. Helix putris L.

< Cochelytra Pérussac, Tabl. Syst., pp. xxxix, 26, 1821.

Tapada Studer, Syst. Verz., p. 11, 1820.

Succinea Deshayes, Encyc. Méth., ii, p. 18, 1830, passim.

> Helisigna Mrs. Gray, Fig. Moll. An., iv, pp. 55, 113, 1859.

< Truellia Pease, P. Z. S., 1871, pp. 459, 472; type T. elongata Pease.

Neritostoma Westerlund, Fauna d. Pal. Reg., ii, v, pp. 1, 2, 1885; S. putris L.

Oxyloma Westerlund, op. cit., pp. 1, 7, 1885; S. dunkeri (Zelebor).

Amphibina Westerlund, op. cit., pp. 1, 8, 1st sp. S. elegans Risso.

Lucena Westerlund, op. cit., pp. 1, 14, 1st sp. S. oblonga Draparnaud.

This genus has been divided into sections on the basis of the denticleation of the jaw, as follows:

Jaw without denticulations. Oxyloma (hungarica).

Jaw with a single median dentine. Amphibina (pfiefferi).

Jaw with a minute median denticle. Lucena (oblonga).

Jaw with three denticles Neritostoma. = Succinea s. s.

According to this scheme S. avara is an Amphibina, S. totteniana a typical Succinea, while S. ovalis (Say) Morse has seven denticles and is unprovided for. The differences among the few species which
have been examined are so great that it is probably better to await a more thorough knowledge of all the species, in the light of which we can judge better whether this character has any systematic value or not. Our American species resemble one another so closely that it seems hardly likely that there are any fundamental differences between them.

**Succinea oregonensis** Lea.

**Range.** — California (to 6,500 feet alt.), Oregon, Washington, and British Columbia.

Victoria, B. C. ! Wallawalla, Wash. !

This species on the Pacific Coast takes the place in the fauna occupied in the East by *S. avara* Say, which it much resembles. The *S. 'oregonensis'* reported from Winnipeg by Hanham was probably a variety of *avara*. The surface has a silky unpolished appearance, from the very fine close wrinkles with which it is covered, and which are characteristic.

**Succinea retusa** Lea.

**Range.** — Northern United States, from Kentucky northward to Canada and British America.

In Manitoba at Carberry, Lake of the Woods and Pembina Mountain; in Alberta at Laggan and Red Deer. Ungava, Labrador ! James Bay at Moose Factory ! Lower Saskatchewan near Lake Winnipeg ! Norway House; York Factory; Fort Resolution, Great Slave Lake! Yukon River near old Fort Yukon, Alaska ! Stewart River, Yukon district ! Dall River, north of the Yukon! Duncan Bay, Discovery Passage, British Columbia.

A widespread and abundant species identified by comparison of the typical specimens or cotypes furnished by the author to the National Museum.
Succinea hawkinsi Baird.

**Range.** — British Columbia and eastward to Manitoba.

Lake Osoyoos, B. C.; Sitka, Alaska; Carberry, Manitoba; not common.

A large species with a produced oblique aperture and acute spire. Quite close to *S. sillimani* Bland.

*Succinea avara* Say.

*Succinea avara* Say, Rep. Long's Exped., ii, p. 260, pl. xv, fig. 6, 1824.

*Succinea avara* Binney, Land and Fw. Sh. N. Am., i, p. 262, fig. 468, 1869.

**Range.** — North America east of the Rocky Mountains from Texas to N. Lat. 62°.

Lac des Mille Lacs to Lake of the Woods; lower Saskatchewan near Lake Winnipeg; Two Creeks, Manitoba; Laggan, Red Deer, Olds, and McLeod, Alberta; Fort Simpson, Mackenzie River in N. Lat. 62°.

*Succinea gronlandica* Beck.

**Range.** — Iceland and Greenland.

This species is rather close to *retusa* Lea but seems sufficiently distinct to be retained.

*Succinea grosvenori* Lea.

**Range.** — North America, east of the Rocky Mts. from Louisiana to British America but not far east of the Mississippi.

Wood Mt., Manitoba; Egg Lake and Red Deer, in Alberta; upper Mackenzie River at Fort Simpson!

1 *Succinea verrilli* Bland (1865; Binney, L. and Fw. Sh. N. Am., i, p. 264, fig. 472) is probably either the young or a dwarf form of this species. It is from Anticosti Id.
The distribution indicated by the literature is rather odd for a shell ranging so far south, but there is no way of clearing up the doubt at present.

**Succinea rusticana** Gould.

**Range.**—Tulare valley, Calif., northward to British Columbia; the variety *alaskana* to Alaska.

Comox, Vancouver Island, B. C. ! Sumas Prairie, Fraser River valley, B. C. !

Variety *alaskana* Dall, nov. Flats near St. Michael, Alaska ! Point Romanof ! Unalaska ! St. Paul, Kadiak Id. !

The Alaskan form is polished, of an olive greenish tinge, with rather inconspicuous lines of growth; with 3 tumid whorls, the general form of *rusticana* as figured by Binney, but shorter and more tumid; length 10, max. diam. 8, length of aperture 6.5 mm. This may prove, with more material, to be a distinct species.

**Succinea nuttalliana** Lea.

**Range.**—Oregon, California, Washington and British Columbia. Victoria, Vancouver Island, B. C.

This species was also reported by Randolph from the Lewes River, Yukon Territory, but in this case the shell was probably the quite similar *S. retusa* Lea.

**Succinea obliqua** Say.

*Succinea greeri* Tryon, Am. Journ. Conch., 11, p. 232, pl. (11) XVII, fig. 8, 1866.

**Range.**—From Louisiana to Hudson Bay and eastward to New England and Gaspé, but not west of the Mississippi Valley.
FAMILY LYMNÆIDÆ

Lac des Mille Lacs to Lake of the Woods! Halifax, N. S.; Dufferin, Manitoba; Lake Winnipeg! Moose Factory, James Bay; Peace River, Athabaska! Great Slave Lake at Fort Resolution! Balena Bay, Newfoundland!

If the identification with Say’s unfigured ovalis were beyond dispute, the latter name is prior and would have to be adopted.

Succinea chrysis Westerlund.

Succinea annexe WESTERLUND, Vega Expd., p. 199, pl. III, fig. 11, 1885.

Succinea chrysis var. aurelia VON MARTENS, Conch. Mitth., II, p. 184, pl. xxxiii, figs. 21–22, 1885.

Range. — Boreal America from Greenland to Bering Strait, and on the opposite shore of the Strait.

Greenland (Posselt); Fort Simpson, Mackenzie River; watershed of the Yukon, near Dawson, Yukon Territory! 30 miles below the Tanana River mouth on the Yukon, Alaska! the Koyukuk River, north of the Yukon! Nulato! Andreafski! and the Yukon delta! Point Romanof! shores of Norton Sound at Egg Island! Besboro Island! Cape Denbigh! Norton Bay! Golofnin Bay! Port Clarence! Konyam Bay on the Asiatic shore of Bering Strait; St. Michael! St. Mathew! St. Paul! and St. George! Islands, Bering Sea; north end of Nunivak Island! the Aleutian chain! Unalaska! Kadiak Island! Sitka! At Chilkat Inlet, Alaska, Krause obtained the variety aurelia von Martens.

This is the commonest and largest land shell of the boreal American region, passing through many mutations, but easily recognizable in all of them; often with a rich coloration varying from olive brown to orange and usually lineated with more opaque lighter axial streaks. I do not regard it as identical with the S. lineata of W. G. Binney, though the species have some characters in common.

Family LYMNÆIDÆ.

Genus Lymnaea Lamarck.

Limnea cochlea LINNÉ, Fauna Svecica, ed. 1, pp. 374, 376, 1746 (not binomial).

Vesica (ex parte) ANONYMOUS, Mus. Calon., p. 58, 1797; Helix stagnalis (and amarula) LINNÉ.

Helix (sp.) LINNÉ, Gmelin, Bolten in Mus. Bolt., p. 109, 1798.
LAND AND FRESH WATER MOLLUSKS

Lymnaeus CUVIER, Regne An., ii, p. 412, 1817.

Lymnus MONFORT, Conch. Syst., ii, p. 262, 1810, L. stagnalis L.

> Lymnula RAPINESQUE, Journ. de Phys., LXXXVIII, p. 423, 1819; = Lymnea of Authors, fide Rafinesque, l. c.

> Onphiscola RAPINESQUE, Op. cit., p. 423, 1819. No species cited, but the only Ohio shell corresponding even moderately to the diagnosis is L. reflexa Say.

Auricularia FABRICIUS, Fortegnelse, p. 94, 1823 (nude name), not of Blainville, 1816.

Leachia JEFFREYS, Linn. Trans., xvi, iii, p. 519, 1833, not of Risso, 1829, or Lesueur, 1821, L. stagnalis (Linné).

> Acella HALDEMAN, Mon. Limn., part 3, p. 6, July, 1841; type Limnea gracilis (Say) Haldeman.

> Polyrythits Meek, Rep. Inv. Fos. Upper Missouri, p. 532, 1876; type Limnæa kingi Meek (Pliocene).

The genus Limnæa as now understood is due to Lamarck, though several authors, including Westerlund as late as 1885, have given credit for it to Bruguière. This has probably arisen from a failure to observe the dates of the different livraisons which contained the plates of the Encyclopédie Méthodique. The plate containing the name Limnæa was not issued until 1816 (though often cited as 1791), and then it was under the supervision of Lamarck, Bruguière having nothing to do with it. The name Limnæa had already been used by Poli, in 1791, for the animal of various unrelated bivalves, but his ingenious quadrinominal system takes the work of Poli out of the category of those which can be cited in nomenclature, except historically.

1 The multitude of group names used for mutations of Limnæa stagnalis and other species by Servain in his 'Lake Balaton' paper, can hardly be regarded as having entered into systematic nomenclature, as they are groups of less value than species, and physiological rather than hereditary, according to Hazay.
The name *Lymnaea* has been spelled in many different ways, the most correct being *Limnaea*, but there seems to be no good reason for changing the original form, especially as no derivation was given by Lamarck. The *Helix stagnalis* of Linné, being the only species mentioned, necessarily becomes the type.

Four years after Lamarck, Schrank gave the name *Galba* to a species which was without doubt the *Buccinum truncatulum* of Müller. It has been referred to *B. palustre* Müller, but a scrutiny of the very careful description of both shell and animal reveals that it agrees with no local species of the group except a young *truncatula*. A little later Montfort separated the *L. auricularia* group under the name of *Radix*, and in 1819 Rafinesque, in a summary of the forms collected on the Ohio River, proposed *Omphiscola* for species which have the peristome reflected over the pillar and body with an umbilical chink between the reflection and the body of the shell. He cites no species, but of the Ohio species only *L. reflexa* Say can be said to agree with the diagnosis. This character is however of minor importance. Rafinesque’s name has been applied to several European species but without adequate grounds, since there is no species of the *Radix* group known in any part of the Ohio system.

The name *Stagnicola* Leach was cited in synonymy by Jeffreys in 1830, in connection with *L. palustris* (Müller), thus antedating *Limnophyta* Fitzinger, 1833, based on the same type. *Stagnicola* was used by Brehm for a bird in December, 1830, but Jeffreys’ paper was issued May 29. Both these names have been loosely used in the literature, but must be restricted to the typical and original forms. If the columnar species like *L. glaber* be separated in a section by themselves, *Leptolimnea* Swainson appears to be the first available name. *Erinna* Adams is a Limneid modified for existence on rocks in rapid streams and waterfalls, the peristome being continued over the body and behind the broad excavated pillar, and the spire shortened, so that the animal may cling tightly to its situs. The descriptions of this form are rather misleading, the so-called ‘lamina’ being merely the pillar. The fossil *Velutinopsis* is more like *Choanomphalus* than *Lymnaea*, judging by the figures. The description of *Tanousia* reads as if it was founded upon an abnormal or monstrous specimen. The reversed physiform *Lymnaea* of the South Sea Islands will be included under *Physastra* Tapparone-Caneffri; a species from Hawaii which is dextral but may be otherwise similar, has recently been shown by Pilsbry to have a somewhat different radula from the ordinary *Lymnaea* of north Europe and America.
Dybowski has recently applied the name *Omphalolimnus* to a species of *Lymnaea* from the Crimea, which in outline resembles *L. stagnalis* var. *arenaria* Colbeau, but which instead of having the axis pervious and the pillar gyrate, as in most species of this type, has the subumbilicate base and raised inner lip of the *Radix* section, to which his *L. lagorii* probably belongs, although it has a more elevated spire than most of the species of this section, being in this respect intermediate between the latter and *Lymnaea* proper.

The existence of fresh water shells in lakes or ponds where the water, through evaporation, is gradually becoming more alkaline, has been shown to be accompanied, in the lake-beds of the Great Basin of the western United States, by a tendency to solidification, thickening and corrugation or ribbing of the shells, regardless of their systematic relations. This goes on until the alkalinity becomes so great that moluscan life is no longer possible. We find in the fresh water Pliocene beds of Utah, *Lymnaea*, *Pompholyx*, *Carinifex*, *Physa* and *Planorbis* exhibiting these changes as we ascend in the beds, until the latter become barren of life. To these modifications we probably owe such forms as *Polyrhytis*, *Pleurolimnæa*, *Vorticifex*, etc. I have shown in another place how such factors may be supposed to act in the case of land shells exposed to alkaline dust on tropical islands such as the Galapagos. While such changes are the result of the direct action of the environment on the individual, and not hereditary or evolutionary, it is nevertheless convenient to recognize the results in the systematic arrangement of the species.

Disregarding synonyms, which can be deduced from the preceding data, the general arrangement of the groups of the genus *Lymnaea* would be about as follows:

Subgenus *Lymnaea* s. s.

Section *Lymnaea* s. s. Shell thin, with an acute and slender spire and expanded last whorl; the axis twisted, forming a (usually pervious) spiral coil without a true umbilicus; the callus on the body closely appressed; the outer lip flaring more or less, simple, sharp, normally without any varical thickening. Type *L. stagnalis* (Linné). Holarctic.

Section *Bulimnea* Haldeman. Shell large and solid, bulimiform, with an impervious axis, a twisted or subplicate pillar, the callus on the body and pillar closely appressed, and the outer lip not thickened or expanded. Type *Lymnaea megasoma* Say. Nearctic.

Section *Radix* Montfort. Shell thin, usually with a short spire and ample last whorl; the axis twisted but not gyrate, the outer lip often expanded, the inner one more or less elevated and continuous across the body, forming a more or less conspicuous umbilicus; the outer lip thin. Type *Lymnaea auricularia* (Linné). Holartic.

The umbilicus in this group varies from a mere chink to a rather large orifice through which a bristle may be passed nearly to the apex of the shell.

Section *Cyclolimnaea* Dall, nov. Shell thin, involute, the last whorl as long as the shell, the outer lip thin, simple, not expanded, the inner lip appressed, the axis not plicate, but with a small umbilical chink. Type *Lymnaea involuta* Harvey. British. The mantle is said to be extended partly over the shell.

Section *Polyrhitis* Meek. Shell like *Radix*, but axially strongly ribbed. Type *L. kingi* Meek. Pliocene, N. Am.

Section *Acella* Haldeman. Shell thin, smooth, acute, extremely slender; the aperture expanded at the margin, the inner lip not appressed, a moderate chink behind it, the axis gyrate, pervious, not plicate; the outer lip simple, sharp. Type *L. gracilis* Jay. Nearctic.

Section *Pleurolimnaea* Meek. Shell like *Acella*, but axially prominently ribbed. Type *L. tenuicostata* Meek and Hayden. Eocene, N. Am.

Section *Galba* Schrank. Shell turrited, the whorls gradually increasing, smooth; the last whorl not inflated; the aperture moderate; the outer lip not expanded or thickened; the inner lip not appressed; the pillar not twisted or plicate, the axis minutely umbilicate. Type *L. truncatula* (Müller). Holartic.

Subgenus *Stagnicola* Leach.

Section *Stagnicola* s. s. Shell elongate, smooth, the whorls gradually increasing, the last whorl moderate; the outer lip sharp, not expanded, with a varical thickening within, in the adult; the pillar distinctly plicate, the inner lip appressed, the axis slightly or not at all perforate. Type *L. palustris* (Müller). Holartic.

Section *Leptolimnea* Swainson. Shell like *Stagnicola* but more cylindrical, with numerous whorls and a small aperture. Type *L. glaber* (Müller). Palearctic.

? Section *Physastra* Tapparone-Canefri. Shell like *Stagnicola* but with a coarse dehiscent periostracum and coiled sinistrally. Type *P. vestita* T.-C. Polynesian.
FAMILY LYMNAEIDÆ

Genus Erinna Adams.

Shell small, with a short spire, a large final whorl; the aperture with a continuous peristome which passes behind a broad somewhat excavated pillar; axis imperforate and the pillar not plicate. Type *E. newcombi* Adams. Hawaiian.

*Incertae sedis.*

*Velutinopsis* Sandberger. Shell almost planorboid, with few, rounded, rapidly increasing whorls; the aperture simple, suborbicular, the peristome sharp, simple, not reflected; the pillarlip broad, not appressed; the axis umbilicate. Type *L. velutina* Deshayes. Pliocene of the Crimea.

*Tanousia* Bourguignat. Shell small ovate conic, closely and almost involutely coiled; the last whorl inflated, subcarinate behind, the aperture contracted. Type *L. zrmanjae* Brusina. Pleistocene of Dalmatia. The group was named *Sandria* by Brusina in 1885, ed. Westerlund.

*Zagrabica* Brusina. Shell ventricose, with a short acute spire and few rounded whorls, rugose, umbilicate, the last whorl ample, with a rotund transverse aperture, and continuous peristome appressed on the columellar margin; the outer lip simple. The type is a Pleistocene fossil. A recent form from the Caspian has been referred to this group by Dybowski, under the name of *Z. brusiniana*.

I have not seen specimens, but the description reads as if the shell might be a member of the *Radix* group which has been modified by life in brackish water.

*Lymnea stagnalis* Linné.

*Lymnea stagnalis* Lamarck, Prodr., p. 75, 1799.

Range.—Europe, the Caucasus, western and northern Asia, the northern United States, Canada and British America.

Lake Superior, Lake Winnipeg! the Saskatchewan River! Carberry, Manitoba; Moose Factory, James Bay! Knee Lake, Keewatin! Slave River, 25 miles below Peace River! Great Slave Lake at Fort Rae! and Fort Resolution! Fort Simpson! and Fort Smith! on the Mac-
kenzie River; Fort Anderson, Lat. 68° N.! and Lake Harrison, Lat. 70° N! Shawnigan Lake, Vancouver Island! and Dall River, Lat. 66° N.! of the Yukon drainage in Alaska. The following additional localities are cited from the literature: York Factory, Keewatin, and the Nelson River; Egg Lake, Alberta; Red Deer, McLeod, and Olds; Lake Isle Lacrosse and Vermilion Lake; Lake Osoyoos, B. C. (but replaced west of the Cascades by L. sumassii, according to J. K. Lord); Syniakwateen Lake, B. C.; lakes in the Kenai Peninsula, Alaska (Wossnessenski); Stewart River, Yukon district (Canadian Geol. Survey).

It seems unnecessary to cite the multitudinous varietal names bestowed on the mutations of this species in Europe. In a wide sense it is one of the most easily recognizable of fresh water shells, as it is one of the most conspicuous of circumboreal species.

Lymnaea petersi n. sp. Plate 11, fig. 3.

Shell extremely thin, of five or more tumid rapidly enlarging whorls; spire acute, the suture deep; whorls rounded, the periphery nearer the preceding suture; shell of a blackish brown, polished, finely sharply spirally striate; periostracum brownish, darker at resting stages; aperture oval, a thin wash of callus on the body; pillar very thin, gyrate, the gyrations pervious; the outer lip not thickened. Height 16; max. diam. 8; height of aperture 8.5; width 5.2 mm.

This very delicate and pretty species appears to belong to the typical Lymnaea in spite of its small size; it has much the aspect of a minute L. randolphi, but has more whorls in less than half the height, and is of quite a different color and without angularity to the whorls.

Lymnaea atkaensis Dall. Plate 11, figs. 8, 10.

Range. — Lake on the island of Atka, Aleutian chain, near Korovin Bay.

Shell with about four ovate whorls rapidly increasing, of a dark olive sometimes purplish tint, very thin, malleated, microscopically reticulated, with obscure revolving ridges; the aperture ovate, not expanded, the margins thin, that on the pillar narrowly reflected;
pillar gyrate, pervious, in the early whorls widely so, a condition concealed in the adult.

This form grows in a region containing little lime, and the shells are extremely thin and often eroded into holes, which exhibit the peculiarities of the axis by which the species is relegated to the typical Lymnaeas, though externally it has much the appearance of a small Radix. The species has been figured in the newer portion of the Conchylien Cabinet, but I have not the reference at hand.

*Lymnaea lepida* Gould.

_Range._—Lake Vancouver, Oregon (Wilkes); near Challis, Idaho (Merriam)!

A species existing near the boundary and doubtless to be found in southern British Columbia.

*Lymnaea* (Bulimnea) _megasoma_ Say.

_Limnea megastoma_ SOWERBY, Conch. Icon., XVIII, pl. II, fig. 12, 1872.

_Range._—Northern New England, Canada and British America to Lat. 57° N.

Lake Superior! Vermilion Lake, H. B. T.; to Etchimamish Lake, in Lat. 57° between the Nelson River and the Height of Land, Keewatin; Bois Blanc Lake, Manitoba!

The British American localities are cited from the literature, and except the last I have been unable to verify them by an examination of authentic specimens.
Lymnaea (Radix) mighelsi Binney.

*Lymnaea catascopium* HaldeMan, Mon. Limn., p. 52, 1842; not of Say.

*Lymnaea emarginata* Say, var. mighelsi Binney, Nylander, Distr. of Limnaea, etc., pls. 1-IV, 1901.

Range. — Aroostook Co., Maine; Province of Quebec; northern Michigan.

The earliest name of this species is *decollata*, which was applied to a stunted variety living in acidulous water which destroyed the early whorls. This name, however, being quite inapplicable to the normal shell, would best be kept for the shells to which it was applied, and retained in a varietal sense. After an examination of Say's types of *L. emarginata* I am quite confident, as species go in *Lymnaea*, that it is distinct from the present form, which I have never seen from the Western region. This species, *L. mighelsi*, is apparently a representative of *Radix*, while the thickening of the outer lip internally in *L. emarginata* var. *canadensis* leads to the suspicion that it is related to *Stagnicola*. Owing to the manner in which various forms of *emarginata* have been summarily united with *L. mighelsi* by reputable students, I shall on the present occasion waive this doubt and proceed to its immediate consideration. It may, however, be pointed out that W. G. Binney seems to have been of the same opinion when, in 1865, he placed *L. emarginata* in the same group as *L. palustris*.

Lymnaea (Stagnicola?) *emarginata* Say.

*? Lymnaeus emarginatus* Say, Am. Conch., VI, pl. 55, fig. i, 1834.

Limnea emarginata HALDEMAN, Mon. Limn., p. 10, pl. 11, figs. 4–5, 1841.

? Limnea serrata HALDEMAN, Mon. Limn., p. 12, pl. 11, fig. 7, 1841 (pathologic specimen, figure copied by Binney, *op. cit.*, p. 52, fig. 78).

**Range.**—Northern United States east of the Mississippi, Canada, and northwestward.

Lakes in northern Maine (Say) ! Lake Champlain and Ontario; Crooked Lake, Emmet Co., Michigan! English River, Keewatin, Hudson Bay! Port Clarence, Alaska (Vega Expd.).

After considerable study I have been forced to the conclusion that several species were identified under this name by Say himself, as well as others. Say’s figure is wretched and does not represent the typical form from Maine, as at first described. The latter is apparently represented by specimens labelled by Say himself, still preserved in the Academy at Philadelphia, and which must be regarded as typical. The shell is small, with an acute spire; one of the specimens has the suture deeply impressed, but not the others, which seem more normal. Westerlund’s figure fairly represents the species; Sowerby’s *L. canadensis*, judging from specimens compared with the types by Mr. E. A. Smith of the British Museum, is probably the same, though the shells are heavier and larger, with the lip thickened internally, and a marked umbilicus. I should not, in default of this comparison and if obliged to depend on Sowerby’s figures, have felt justified in uniting them.

**Limnæa (Radix) binneyi** Tryon.

**Range.**—Northern United States west of Lake Huron and the adjacent British possessions.

Lake Higgins, southern Michigan! Lake Houghton, northern Michigan! east of Fort Colville, Wash! Fort Vancouver, Columbia River! Sumas Prairie, B. C! Vancouver Island; Clear Lake, Athabaska, N. Lat. 56°! Lake Isle Lacrosse, Athabaska! English River, Manitoba!

This species appears to be quite recognizable but has been frequently distributed under the name of *L. sumassi* or *ampla*, with the latter of
which Tryon himself at one time confounded it. It has a short spire with appressed or moderately conspicuous suture, ovate form, tumid whorls, pale color, well marked umbilicus, and fine spiral striation. The largest specimen I have seen measured 27 mm. high and 18 mm. in maximum diameter; but the average adult is about 24 × 15 mm. I have not seen any specimens angulated at the shoulder.

*Lymnaea (binneyi var.?)* preblei Dall, nov. Plate 1, figs. 1, 2.

A shell which when young is almost identical with *L. binneyi*, and which may prove merely a giant growth of it, occurs in the Hudson Bay drainage. When full grown it has six whorls, with much the same contour as *Bulimnea megasoma*, the last whorl being much the largest, moderately expanded, and somewhat produced in front. The umbilicus is deep and partly hidden by the reflected pillar lip, which is continuous and more or less raised across the body. There is no fold on the pillar. The surface, when in perfect condition, is minutely but sharply saginate by the intersection of axial and spiral striae, and is often malleate besides. The shell is nearly white or pale straw color.

Adults measure:

*Range.* — English River, Manitoba (Kennicott)! Knee Lake, Kee- watin (E. A. Preble)! 

This form is remarkable for its size, its surface, and its deep umbilicus. The resemblance of its profile to that of *L. megasoma* is so marked that one wonders whether some of the records of the latter species from high northern localities may not have been based on specimens of this form. They are easily separated, however, if one pays attention to the other characters, and the present form probably never attains the solidity and rich coloration so characteristic of *megasoma*.

**Fig. 47. Lymnaea columella.**

*Lymnaea (Radix?) columella* Say.

*Limnea columella* HALDEMAN, Mon. Limn., p. 38, pl. xii, figs. 13-15, 1842.

—BINNEY, Land and Fw. Sh. N. Am., ii, p. 32 (ex parte), fig. 38, 1865.
Range.—Manitoba to New England, New Mexico, and Georgia. Lake Superior! Lake Winnipeg (Rich)!

This attractive species is readily recognized by its Succinea-like form and fine spiral sculpture. The synonymy as given by Binney and others seems to need revision. I am not of the opinion that this form belongs properly in the Radix group, as it has several features in common with Stagnicola, notwithstanding the form of the shell. An anatomical examination will decide the question.

Lymnaea (Radix) randolphi F. C. Baker, Plate 1, figs. 3, 4.

Shell large, thin, angulate or subangulate at the shoulder; constricted strongly at the suture, narrowly and deeply umbilicate, whorls about four, rapidly increasing in size but frequently decollate; when entire the spire is less in length than the aperture but the proportion is variable; in conformity with the sutural constriction the posterior angle of the aperture is usually somewhat narrow, the apertural margin continuous over the body, with a narrow deep umbilicus over which the pillar lip may be reflected. The pillar is sometimes slightly sinuous but not plicate, the surface may be smooth and polished, malleated, spirally threaded or minutely reticulated by axial and spiral lines. The periostracum is pale, but usually has a dark line at resting stages; the outer lip is hardly expanded though often a little patulous in front; it is never internally thickened. Measurements:

Range.—Lake near Cosmos River, north of the Kowak River, Alaska, about N. Lat. 68° (Lieutenant Stoney) ! Kowak River, Alaska (Stoney) ! Nushagak River, Alaska ! Lake Marsh ! and Lake Lindeman, Yukon Territory ! Lake La Hoche, British Columbia ! East of Fort Colville, Wash. !

This form is very recognizable, with its angular whorls and deeply constricted suture. A specimen from near Fort Colville, figured by Binney as a possible variety of L. sumassi Baird (op. cit., p. 43; fig. 58), may prove a feebly angulated and unusually short spired specimen of this species. I have received it under the names ampla, sumassi, etc., from several Pacific Coast correspondents, and a large number of mostly defective specimens were obtained by the expedition into northwestern
Alaska commanded by Lieutenant Stoney, U. S. N. The true L. sumassii Baird is apparently a Stagnicola, but the present species belongs to Radix. It is not in the least like L. mighelsi (ampla Mighels) though often given that name.

**Lymnaea (Acella?) kirtlandiana** Lea.

**Range.** — Ohio to Nebraska, and northward.

Poland, Ohio! Iowa River, Iowa! Apple Creek, Nebraska! Pic Lake, north of Lake Superior, in western Ontario!

The original types of Lea's _Limnaea exilis_ are in the National Museum, and after a careful examination of them I am inclined to believe that they are somewhat abnormal dead specimens of this species rather than a mutation of _L. reflexa_, as supposed by Binney; unless we extend _L. reflexa_ to cover the whole group, which seems to me unwarranted. _L. lanceata_ is an immature specimen of what was earlier called _kirtlandiana_ by Lea. The figures of both these forms in Binney's work are uncharacteristic, especially that of _lanceata_, which shows nothing of the "flatness of its whorls" referred to by Gould in his remarks.

These shells have all the characteristics of _Acella_ except that they are less fragile, larger, and darker colored. They have the gyrate pillar of _Lymnaea_ and not the plicate columella of _Stagnicola_, which in other respects they recall. Until an exhaustive anatomical and experimental study of these animals is made, all group-references must be merely tentative.

**Lymnaea (Galba) truncatula** Müller.

_Buccinum truncatum_ Müller, Verm. Terr. et Fluv., ii, p. 130, 1774 (Europe).

_Limneus minutus_ Draparnaud, Tableau, p. 51, 1801; Hist., p. 53, pl. iii, figs. 5-6, 1805 (France).

**Range.** — Europe, northern Asia and America.
FAMILY LYMNAEIDÆ

Bering Id., Commander Islands, Bering Sea! Kadiak Island, Alaska! ponds near Yakutat Bay, Alaska (Kincaid)! Fort Simpson, Mackenzie River (Kencicott)! near Brandon, Manitoba (Christy)! Oregon (Nuttall); Hannah Bay (out of James Bay) near Moose Factory!

Specimens absolutely identical with those from Europe have been collected from the indicated localities. It is quite likely that some of the specimens reported by collectors under the name of *humilis* or *desidiosa* may have belonged to this species. The form called *ferruginea* by Haldeman seems to differ only by having the pillar lip more closely appressed, a character which any large series will show to be inconstant in individuals among themselves as well as in the same individual in different stages.

**Lymnæa (Galba) humilis** Say.

Limnea humilis (Say) Haldeman, Mon. Limn., p. 41, pl. 13, fig. 1, 1842 (syn. exclus.). — Binney, Land and Fw. Sh. N. Am., 11, p. 63, fig. 99, 1865.

.Range. — From Georgia and Kansas northward. Lake Superior; Lake Winnipeg; Brandon; and Pembina Mt., Manitoba.

I have been unable to examine any authentic specimens from north of Lat. 49°, and the above localities are cited from the literature.

**Lymnæa (Galba) desidiosa** Say.

Limneus desidiosus Say, Am. Conch., vi, pl. 55, fig. 3, 1834.

Limnea desidiosa HaldeMan, Mon. Limn., p. 31, pl. x, 1842 (ex parte). — Binney, Land and Fw. Sh. N. Am., 11, p. 49, fig. 68, 1865.

The above localities are cited from the literature.

**Lymnæa (Galba) galbana** Say.

**LAND AND FRESH WATER MOLLUSKS**

*Limnea traskii* Tryon, Proc. Acad. Nat. Sci. Phila., for 1863, p. 149, pl. 1, fig. 13, 1863.—Binney, Land and FW. Sh. N. Am., ii, p. 60, fig. 94, 1865.—Tryon, Mon. Limn., p. 119, pl. 17, fig. 3 (not p. 96, nor fig. 2), 1872. (Mountain Lake, near San Francisco, Calif.) Not *L. traskii* Lea, 1864, nor *L. proxima* Lea, 1864.

**Range.**—Pleistocene marls of Franklin, New Jersey; of Anticosti Island! of Ottawa, Canada! and of the left bank of the Yukon River, Alaska, below old Fort Yukon! Recent, at the Grand Rapids of the Saskatchewan River, near Lake Winnipeg! Grindstone Creek, Nebraska! Centre City, Pennsylvania! Vancouver, Columbia River! and near Monterey, California! Alaska (von Martens); Attawapiskat River, S. E. Keewatin! (McInnes).

This small species has the spire acute and short, the last whorl disproportionately swollen and usually shouldered. It appears to have flourished during the melting of the glacial ice, and to the muddy waters of the period its peculiarities may be due. The recent form seems less abnormal on the average.

There are two species which have been called *traskii*—the present one, with which Tryon afterward mistakenly united *L. proxima* Lea, a much larger species; and *L. traskii* Lea, later called *tryoni* and *tryoniana* by Dr. Lea, which is a *Stagnicola*.

**Lymnaea (Galba) holbolli** (Beck) Möller.

*Lymnaea (Limnophysa) holbolli* Beck, Index, p. 111, 1838; nude name. Greenland.

**Range.**—Godhaab, Greenland.

This has the appearance of a large *L. truncatula*, but may be merely a depauperate variety of the next species.

**Lymnaea (Galba) vahlíi** (Beck) Möller.

*Lymnaea (Limnophysa) vahlíi* Beck, Index, p. 111, 1838; nude name. Greenland.

*Lymnaea vahlíi* Möller, Index, Moll. Grönl., p. 4, 1842.

**FAMILY LYMNAEIDÆ**

*Limnaea* (Limnophyta) senegalensis Beck, Index, p. 111, 1838 (nude name), fide Möch, op. cit., p. 35, footnote.

**Range.** — Greenland to Alaska and south to Minnesota and British Columbia.

Ft. Resolution! and Ft. Rae, Great Slave Lake! Moose River, at Moose Factory, Hudson Bay! Greenland (many localities)!

Ungava, Labrador! Watoga, Canada! Minnesota (Lapham)! Stewart and Dall Rivers, north of the Yukon, Alaska! St. Michaels, Norton Sound, Alaska! headwaters of the Yukon in Lakes Bennett, Marsh, and Lindeman! Loring, Southeastern Alaska, on Behm Canal!

Shawnigan Lake, British Columbia! Headwaters of the Liard River in Lakes Finlayson and Frances! Hannah Bay near Moose Factory!

Making the usual allowances for variation, this is a fairly well discriminated species, which frequently has been identified as *L. desidiosa*, *palustris*, etc. The largest are more fragile, smaller and paler than *L. palustris*, and not especially similar to it. I have had the advantage of being able to consult a very large series of authentically named Greenland shells, received from Möch and others, as well as the fine Arctic series in the National Museum. Most of the specimens are microscopically wrinkled on the surface, like *L. palustris*, but this character is not absolutely constant.
**Lymnaea (Stagnicola) palustris** Müller.

*Buccinum palustre* MÜLLER, Verm. Terr., 11, p. 131, 1774.

*Lymnaea palustris* DRAP., Hist., p. 52, pl. 11, figs. 40–42, 111, figs. 1–2, 1805.

---

**FIG. 56, a–f. Lymnaea palustris** Müller vars. **FIG. 56, g. var. rowelli** Lea from Pacific Coast.

*Lymnaea fragilis* HALDÉMAN, Mon. Limn., p. 20, pl. vi, pl. xv, fig. 1, 1842; not of Linné.

*Lymnaea expansa* HALDÉMAN, Mon. Limn., p. 29, pl. ix, figs. 6–8, 1842 (pathologic mutation).

**Range.**—Circumboreal. Northern United States and Canada.

This well known species is almost universally distributed in the quiet waters of boreal America, and in the Pleistocene marls. The distinctions which have been relied on to separate *L. haydeni* Lea, and *L. expansa* Haldeman, are due to pathologic mutations. *L. nuttalliana* and *proxima* Lea, are trivial varieties.

**Lymnaea (Stagnicola) reflexa** Say.

*Limneus umbrosus* Say, Am. Conch., IV, pl. 31, fig. 1, 1832 (new name for *elongatus* Say).

**Range.** — Northern United States and Canada.

Prairie Lake, near Red River of the North; and Beaver Creek, Manitoba.

This species barely crosses the boundary and may be one of those captured by the northward drainage when the headwaters of the Mississippi were interrupted and turned northward by the changes in the land levels of this region which have been elucidated by the late General G. K. Warren.

**Lymnaea (Stagnicola) catascopium** Say.

*Lymnea catascopium* Say, Nicholson's Encycl., Am. ed., II (no pagination), pl. 2, fig. 3, 1817 (Delaware River).

*Lymneus catascopium* Say, Am. Conch., VI, pl. 55, fig. 2, 1832.

*Lymnea cornea* VALENCIENNES, in Humboldt and Bonpland, Rec. d'obs. de Zool., II, p. 251, 1832.

**Range.** — *L. catascopium*: Northern United States to the Rocky Mountains, Canada and northward; var. *sumassi*: Idaho, Washington and British Columbia.

Ottawa, Canada! Ungava, Labrador! Lake Winnipeg, Manitoba! Hudson Bay drainage of Keewatin! Moose River at Moose Factory,
Hudson Bay! Fort Resolution, Great Slave Lake! Winisk, Kawinogans, and Attawapiskat Rivers, S. E. Keewatin! (McInnes).

Quite variable and frequently confounded with L. adelinae, L. bulimoides, L. solida, etc. The Pacific Coast form is quite close to the typical form of the species, but is thinner, less uniform, and sometimes larger. Binney's figure 57 is made from a specimen probably of a rather swollen variety of palustris.

*Lymnaea (Stagnicola) adelinae* Tryon.

*Limnaea adelina* Tryon, Mon. Limn., p. 82 (108), pl. xviii, fig. 6, 1872 (San Francisco, Calif.).

Range. — California to Vancouver Island, B. C.

A small species, recalling *L. bulimoides* rather than *catascopium*, and perhaps identical with Lea's original *bulimoides*, as indicated by his types, but not with *L. techella* Haldeman, which is very generally labelled *bulimoides*.

*Shell* small, translucent, dark amber color, with a darker line at resting stages; smooth, except for fine lines of growth, brilliantly polished; whorls four, tumid, rapidly increasing, separated by a pronounced suture; spire short, rather obtuse; aperture ovate, longer than the spire, with a very thin wash of callus on the spire, the pillar lip slightly reflected, with a small perforate umbilicus behind it; pillar straight, with no twist or fold, outer lip thin, sharp. Length of shell 11; of aperture 7; breadth of shell 8.5; of aperture 4.5 mm.

Range. — Nushagak, Bristol Bay, Alaska.

This shell is so elegantly polished that it may be an *Amphipeplea*. It has the rich dark amber color of some Succineas. I have seen but
one specimen, but some young shells from Sonoma Co., Calif., collected by Hemphill, may belong to it. The latter are proportionally stouter and are of a pale straw color. The polish of the surface and the straight pillar are alike in both, yet I hesitate to unite them. No other American species has an equally polished surface so far as I have observed.

Lymnaea (Stagnicola) bulimoides Lea.

Range. — Oregon, California, Texas, New Mexico, Dakota, the United States west of the Mississippi (and northward?)

Oregon! (Nuttall) Columbia River near Fort Vancouver, Wash.! Moose River at Moose Factory, Hudson Bay (Drexler)?

This species has been generally confounded with *L. techella* Haldeman, which seems to be distinct, having a more stumpy form and larger umbilicus, recalling, as Binney observes, his *Bulimulus pilula*. According to Lea’s types, very few of the localities cited for this species, away from the Pacific Coast, are reliable. I suspect the shell from Hudson Bay, collected by Drexler, is a young *catascopium* or *caperata* and not the true *bulimoides*.

Lymnaea (Stagnicola) caperata Say.

*Lymnaea caperata* HALDEMAN, Mon. Limn., p. 34, pl. XI, figs. 1–9, 1842.

Range. — Northern United States, west to the Rocky Mountains and northward.

Manitoba; at Pine Creek, Pembina, and Lake Winnipeg. Alberta; at Red Deer and McLeod. The lower Saskatchewan near Lake Winnipeg. Hudson Bay drainage at Moose Factory. I feel strong doubts as to the validity of this species, which may prove entirely heterogeneous.

Lymnaea (Stagnicola) anticostiana n. sp. Plate II, figs. 4, 5.

Shell acute, slender, with a blunt reddish nucleus and seven well-rounded whorls; suture deep, the whorls slowly enlarging; the last
whorl subcompressed laterally; aperture elongate-ovate, about $2\frac{1}{4}$ times its length being equal to the length of the shell; margin thickened, and continuous over the body, reflected over an umbilical chink behind the pillar but not quite closing it; pillar with a marked fold; surface with close-set fine axial elevated lines in harmony with the lines of growth, and crossed by microscopic revolving striæ which sagrnitate the surface; there are also malleations, obscure sparse revolving ridges, etc., on individual specimens. Length of shell 19; aperture 7.0; max. diam. 7.0, of aperture 4.5 mm.

Range.—Pleistocene marl of Marl Lake, Anticosti Island (Sir William Logan and Dr. J. Schmitt). Recent?

This interesting species resembles somewhat L. desidiosa, to which it has usually been referred, but it has two more whorls and a more slender and elevated spire, and in most specimens a more parallel-sided aperture. I am unable to say whether it occurs in the recent state, but the numerous specimens I have seen are all fossils. Dr. Lea had labelled his specimens 'L. acuta Lea,' doubtless forgetting his own species of the same name, which is a very different shell.

Uncertain Species.

There are several nude names in the literature which cannot be identified and, yet may puzzle the student who is unaware that they have not been described. Of such are L. fossaria J. de C. Sowerby (1836), in Richardson's Fauna Boreali Americana; L. petitii Beck (1838), listed from Newfoundland in his 'Index'; and L. opacina Bell (1858), listed in the Annual Report of the Canadian Geological Survey.

Genus Planorbis Müller.

Corentus Adanson, Hist. Sénégal, p. 7, 1757 (not binomial), sp. figured resembles P. parvus Say.

= Planorbis Montfort, Conch. Syst., II, p. 270, 1810, selects as type P. corneus L.

< Anisus STUDER, Syst. Verz., p. 23, 1820 (= Planorbus + Physa).

> Anisus FITZINGER, Verz., p. 111, 1833; not of Dujardin, 1821.

> Spirulina HARTMANN, Syst. Uebers., tab. 1840. (Nude name.) No type cited.

Subgenus Planorbus s.s.

Type Planorbus corneus Müller.

(Synonymy of the group given under the generic name.)

Section Planorbina Haldeman.

Menetus FISCHER, Man., p. 509, 1883; P. guadeloupensis Sowerby; not Menetus Adams, 1855.

Anisus GRAY, P. Z. S., 1847, p. 181; P. olivaceus Spix; not Anisus Studer, 1820.

Subgenus Helisoma Swainson.

Helisoma SWAINSON, Malac., p. 327, 1840; P. bicarinatus Sowerby.

Section Piersoma Dall, nov.

Helisoma (sp.) Auct., not of Swainson; P. trivolvis Say.

Section Planorbellula Haldeman.

Subgenus Tropidiscus Stein.

Tropidiscus Stein, Schn. u. Muscheln Berlins, p. 76, 1850; P. complanatus Stein (= marginatus Drap. + umbilicatus Müller).

Anissus Fitzinger, Verz, p. 111, 1833, ex parte, not of Studer, 1820, nor Dujardin, 1821.

> Diplodiscus Westerlund, op. cit., p. 115, 1897, 1st sp. P. vortex Linné.

Section Paraspira Dall, nov.

Spirorbis Swainson, Malac., p. 337, 1840; P. rotundatus Poiret (+ P. vulgaris Swains.), not Spirorbis Daudin, Vermes, 1800.

Planorbis (sp.) Agassiz, in Charpentier, Fauna Helv., p. 21, 1837.

Anissus (sp.) Fitzinger, Verz, p. 111, 1833; not of Studer, 1820.

Subgenus Hippeutis Agassiz.

Section Menetus H. and A. Adams.

Section Drepanotrema Crosse and Fischer.

Section Bathypomphalus Agassiz.

*Polygymus* Gray, P. Z. S., 1847, p. 181; *P. contortus* Müller; not of Beck, 1837, nor *Polygymus* Say, 1818.

*Discoidina* Stein, Schn. u. Muscheln Berlins, p. 82, 1850; *P. contortus* Müller.

Subgenus *Gyraulus* Agassiz.

*Nautilina* (pars) Stein, Schn. u. Muscheln Berlins, p. 80, 1850.

Section Armiger Hartmann.

*Nautilina* (sp.) Stein, Schn. u. Muscheln Berlins, p. 81, 1850.

Section Torquis Dall, nov.

Type *P. parvus* Say.

(Incerte sedis.)

? Section Heterodiscus Westerlund.

? = *Planorbina* Haldeman, 1842, q. v.

The genus *Planorbis* is frequently ascribed to Guettard or Geoffroy, neither of whom accepted (in the papers where this name appears) the Linnean nomenclature. If we are to cite non-Linnean authors we must go back much further, for Petiver used the name in 1702 for a species which Linné afterward named *Helix spirorbis*. Another non-Linnean name is *Coretus* of Adanson, which he applied to a minute species an eighth of an inch in greatest diameter. Gray in 1847, by some error cites *Planorbis corneus* as Adanson’s type, which
is, of course, absurd. The first author to introduce *Planorbis* to binomial literature was O. F. Müller, but as he used it, it was applicable to all aquatic Pulmonates with filiform tentacles, thus including *Physa*. Cuvier in 1798 cited three species, of which *P. corneus* was the first and *P. cornu-arietis* the second. In 1799 Lamarck cited the second species, and repeated this citation in 1801. But *P. cornu-arietis*, of which the soft parts and operculum were then unknown, does not agree with Lamarck’s diagnosis and cannot be accepted as a type of the genus *Planorbis*. Draparnaud names no types, and only in 1810 does Montfort establish definitely the type of the genus as *P. corneus*. Subsequent selection of other types by later authors is, of course, of no effect. *Anisus* Studer was an exact synonym of *Planorbis* Müller, not Montfort, but Fitzinger, in 1833, made an effort to retain the name for a section of the true Planorbes. It is probable, however, that the name, which was intended to comprise two older genera already named, should be entirely eliminated from accepted nomenclature, as a gross violation of the rules. At any rate the name was used for a beetle by Dujardin in 1821, and no subsequent use of it is advisable for Mollusks.

Little is known of the anatomical characteristics of the various species, but much similarity is noted among those for which data are available. As to the shells, a wide variation is observable in form and sculpture, though as usual the peripheral species grade toward each other in the several groups. The great majority of the species present the peculiarity of the whorls rising above the original apex, which becomes basal, the shell (apparently sinistral) thus becoming what has been called ultra-dextral. The most obvious characters of the latter may be contrasted as follows:

Subgenus *Planorbis* s. s. Shell discoid, ultra-dextral, large, with a moderate number of gradually enlarging whorls rounded above and below; the aperture slightly and gradually expanded, with its margin simple and sharp. Type *P. corneus* Müller.

Section *Planorbina* Haldemann. Shell like *Planorbis* s. s. but vertically compressed, with smaller and more numerous whorls and a very oblique aperture. Type *P. olivaceus* Spix.

Subgenus *Helisoma* Swainson. Shell of moderate size, few whorled, the whorls carinate above and below and rapidly enlarging; spire and base funicular, aperture suddenly expanded, with a thickened peritreme. Type *P. bicornatus* (Say) Sowerby.

There is no doubt that Sowerby’s and Say’s species are identical. I am unable to find distinctive characters in figures or diagnoses which
would differentiate *Taphius* Adams from *Helisoma*; and *Anisopsis* Sandberger, from the Jura, is very similar, though the aperture is not preserved in the fossils and may have been simple.

Section *Pierosoma* Dall. Shell large, high, with few transversely sculptured whorls; the early whorls carinate and flattened above, funicular below; in the adult the flattened apex is usually depressed below the upper level of the ultimate whorl; the aperture is suddenly expanded and thickened. Type *P. trivolvis* Say.

Section *Planorbella* Haldeman. Like *Helisoma* but smaller, with more numerous whorls, with the last whorl strongly constricted behind a campanulate aperture; a flattish or even slightly convex upper surface; the base funicular. Type *P. campanulatus* Say.

The *P. multivolvis* Case differs from the type of *Planorbella* chiefly by its more numerous and closely coiled early whorls. In both a second year's growth shows a varix due to the retention of the aperture of the preceding year. Two preoccupied names were applied to *P. multivolvis* by Adams, but a study of specimens leads to the conclusion that its separation is unwarranted.

Subgenus *Tropidiscus* Stein. Shell depressed, the adult periphery angular or carinate, the aperture oblique, slightly expanded, simple. Type *P. umbilicatus* Müller (+ *P. complanatus* Stein).

Section *Tropidiscus* s.s. Shell moderately large and with comparatively few rapidly increasing whorls of which the junior portions are not keeled. Type *P. umbilicatus* Müller.

This subgenus was called 'Gyrorbis Agassiz,' by Moquin Tandon, but Agassiz never proposed any such genus or group, the name *Gyrorbis* having been applied to a subdivision of *Valvata* by Fitzinger. Moquin Tandon's error was copied by Gray, and later by Westerlund, who, still later, having become aware that Fitzinger's name existed, proposed for the group already named by Stein, the name *Diplodiscus*; which naturally becomes a synonym of *Tropidiscus* Stein. Nevertheless, since Westerlund arranged his really typical 'Gyrorbis' under *Tropidiscus*, and grouped under his new name the species of which *P. vortex* is an example (though without mentioning any type) and gave a suitable diagnosis, it may not be stretching the rules of nomenclature too far to retain his name for the following section.

Section *Diplodiscus* Westerlund (restricted). Shell small, with numerous slowly enlarging whorls keeled or angulate from the beginning. Type *P. vortex* Linné.
Section *Paraspira* Dall, nov. Shell resembling *Diplodiscus*, but with the whorls rounded throughout, and the aperture simple, hardly expanded. Type *P. rotundatus* Poiret.

Subgenus *Hippeutis* Agassiz. Shell small, lenticular, with a small number of rapidly increasing whorls, the last enveloping a large part of the preceding whorl; apex slightly depressed, base with a narrow umbilicus, aperture oblique, with a thin sharp margin. Type *P. fontanus* Lightfoot, European.

Section *Drepanotrema* Crosse and Fischer. Shell resembling *Hippeutis*, but less depressed, the whorls with a rounded periphery widest at the base, giving a domelike profile, umbilicus variable, from narrow to very wide. Type *P. yzabalensis* C. and F. This group occurs in the Antilles, Mexico, Central and South America, where it represents the Palearctic *Hippeutis*.

Section *Menetus* H. and A. Adams. Like *Hippeutis*, but the last whorl not enveloping the preceding whorls to any marked extent. Type *Planorbis opercularis* Gould.

Section *Bathyomphalus* Agassiz. Shell like *Drepanotrema*, but with numerous closely coiled whorls, a flattish summit with the periphery nearer to it than to the base, the umbilicus moderate, exposing less of the coil than the summit shows. Type *P. contortus* Drap.

Subgenus *Gyraulus* Agassiz. Shell small, flattish, with few, rapidly increasing whorls, fully exposed above and below, with a nearly median periphery, spirally striate and hispid; aperture simple, sharp-edged, oblique. Type *Planorbis albus* Müller.

Section *Torquis* Dall, nov. sect. Like *Gyraulus* s. s. but with more rounded, less rapidly increasing whorls, not hispid or spirally striate, the aperture expanded and slightly thickened in the adult. Type *P. parvus* Say.

Section *Armiger* Hartmann. Shell small, with few, rapidly increasing, costate whorls, the costæ projecting at the periphery; the form in a general way like *Gyraulus*.

A discussion of the species follows.

*Planorbis* (Planorbina) *glabratus* Say.

*Planorbis lentus* Say, Am. Conch., vi, pl. iv, fig. 1, 1834 (New Orleans).

This species is by no means always polished, and on a dull specimen of it I believe the later *P. lentus* Say to have been founded, though the latter name has been widely misapplied to senile specimens
of *trivolvis* such as occur in the north and east, if not throughout the range of the latter.

**Planorbis (Helisoma) bicarinatus** Say.

*Planorbis bicarinatus* Say, Nicholson's Encycl., 1st ed., vol. 11 (no pagination), No. 2, pl. 1, fig. 4, 1817 (Lake Erie); not of Lamarck, 1822. — Binney, Land and Fw. Sh. N. Am., II, p. 123, fig. 205, 1865.

*Helix engonata* Rackett, 1822; + *Planorbis engonatus* Conrad, 1834.

**Range.** — The United States east of the Rocky Mountains; eastern Canada.

Lake Superior to Lake Winnipeg! Lake Manitoba; Moose Factory, Hudson Bay! the lower Saskatchewan River at Grand Rapids! Knee Lake, Keewatin! Portland, Oregon! Yaqui River, W. Mexico!

This well defined species has probably been carried down stream from the sources of the Columbia River, in the same manner as some other east American species. It cannot be regarded as permanently established on the Pacific slope, as yet. It varies considerably in size, and for exceptionally developed specimens from Benzie Co., Mich., Walker has proposed the varietal name *major*.

**Planorbis (Pierosoma) corpulentus** Say.

*Planorbis corpulentus* Say, Long's Exp., ii, p. 262, pl. xv, fig. 9, 1824 (not of Binney *et al.*) — Bryant Walker, Nautilus, XIII, No. 12, April, 1900, pp. 133-138.

**Range.** — Northern Ontario from Lake Simcoe to Rainy Lake, Lake of the Woods, Winnipeg River and Lake! to Vermilion Lake, Lat. 56° 30', in Athabaska.

Knee Lake, Keewatin! Isle à Lacrosse Lake! and English River! Rat Portage; northern Michigan and Minnesota.

This well marked species was unknown to Binney, and has been united mistakenly with *trivolvis* and others. It belongs to the colder northeastern portion of the continent and its complete range is yet unknown. It has not been identified from the region west of the Rockies. Mr. Walker’s note on this species may be consulted with profit.

**Planorbis (Pierosoma) binneyi** Tryon.

*Planorbis binneyi* Tryon, Am. Journ. Conch., III, p. 197, 1867. — Halde- man, Mon. Limn., 19, pl. iii, figs. 7-9, 1844. — Binney, Land and Fw. Sh. N. Am., II, p. 103, fig. 175, 1865.
Range.—West of the Rockies and east of the Cascade Mountains on the Pacific slope.

Oregon (Nuttall); Lewis or Snake River, Oregon! Clear Lake, Calif.! In British Columbia in eastern Kootenai Lake, Lake Siniakwateen, and Osoyoos Lake!

As pointed out by Binney, this is quite distinguishable from any form of *trivolvis*; it differs from the true *corpulentus*, with which it was long confounded, in its sparser and less regular axial sculpture, larger and less campanulate aperture, and in the greater distance of the carina from the axis. Its whorls increase more rapidly than in *P. traskii* Lea, or even *P. ammon* Gould,1 and its sculpture is markedly coarser and less regular than in either of the two last cited. It is not known north of British Columbia or east of the Rocky Mountains.

![Figs. 66, 67. Planorbis binneyi, showing animal and shell.](image)

**Planorbis (Pierosoma) trivolvis** Say.

*Planorbis trivolvis* Say, Nicholson’s Encyc., 1st ed., II (no pagination), pl. II, fig. 2, 1817; Am. Conch., vi, pl. 54, fig. 2, 1834 (French Creek, Lake Erie).

*Planorbis macrostomus* Whiteaves, 1863 (abnormal); + *P. lentus* Gould, and many other writers, but not of Say; + *P. tumens* various California writers.

*Planorbis subcrenatus* Carpenter, P. Z. S., 1856, p. 220.

Range. — The typical form belongs to the entire Atlantic drainage of North America and the Mississippi Valley and northward to the Etchimamish River.

English River, Keewatin; Lake Winnipeg, Manitoba; Cypress Hills! Assiniboia; Prairie Lake, Red River of the North!; the Saskatchewan River, Laggan, Egg Lake, Red Deer, McLeod, and Olds, Alberta; Lake Isle Lacrosse, Athabaska; Great Slave Lake, at Fort Resolution! and the Mackenzie River at old Fort Simp-

1These two species, judged by their types, which are before me, are sufficiently distinct from any of those which have been confounded with them. Indeed the true *P. traskii* from Kern Lake, Calif., is one of the most remarkable species in our fauna. It was also found by me at Stockton, Calif., and seems to have been unknown, autoptically, to Binney.
son! (N. Lat. 62°). We have it from Moose Factory! the Slave River 25 miles below Peace River! Lake Winnipeg! the Grand Rapids of the Saskatchewan River! and hundreds of more southern localities.

The variety subcrenatus Carpenter (Oregon, Nuttall) occurs in British Columbia west of the Cascades; being, according to J. K. Lord, replaced east of them by P. binneyi. We have it from the Puget Sound drainage! Lake La Hoche! and Sumas Lake, B. C.! A distorted variety (disjectus Cooper) is reported from Lake Tahoe, Calif., at a height of 6,247 feet above the sea. The young shell was described from Pueblo Valley, Oregon, by Tryon in 1865, as P. oregonensis. In 1870 Cooper called the more common adult (but not senile) form P. occidentalis, and later confounded it with the Mexican P. tumens Cpr., and gave it a range in California from Kern Lake, Tulare Co., north to Puget Sound, and, in the coast drainage, to San Francisco Bay. There is a doubt as to whether Planorbis hornii

Tryon (1865), from "Fort Simpson, British America," came from Fort Simpson on the Mackenzie River, or Fort Simpson, British Columbia; but the figure looks more like the Pacific variety, of which it is probably only a mutation. We have specimens from various places in California, and Wallawalla, Wash., labelled P. hornii which are merely a depauperate form of subcrenatus.

On the other hand, from the Dall River, a northern affluent of the Yukon in Alaska, in N. Lat. 66°, we have the typical form of trivolvis
stretching westward with the Yukon drainage! I have never seen any specimens corresponding exactly to Tryon's figure of *P. hornii*, but the variations I have seen of *P. subcrenatus* often approach it so closely that I have little doubt of their identity. *P. macrostomus* seems, from an examination of the types, to be a form of *trivolvis* which has survived a year longer than usual, in a locality where it was not stinted in lime, resulting in a remarkably fine shell with richly colored aperture.

**Planorbis (Planorbella) campanulatus** Say.

*Planorbis bellus* Lea, 1844 (immature shell) + *P. complanatus* Miller Christy, 1885.

**Range.** — The type: New England to Tennessee, Florida and northward; Anticosti Island! Lake Superior to the Saskatchewan; L. Winnipeg, Red River of the North, Nelson and English Rivers; Moose Factory! Great Slave Lake, N. Lat. 62°; Lake of the Woods!

Variety *rudentis*: Knee Lake, Hayes River, Kee-watin, N. Lat. 55° (E. A. Preble)!

This well known species is confined to the Atlantic, Mackenzie, and Hudson Bay watersheds, and has not been reported north of Great Slave Lake. So far as the specimens examined go to show, it is rather remarkably uniform in its characters, the number of whorls remaining always about the same, though the actual size varies with the food supply and healthfulness of the environment.

A form which may prove distinct, or a variety of this species, was collected by Mr. Preble at Knee Lake. The comparative measurements are:

<table>
<thead>
<tr>
<th>Type</th>
<th>Whorls</th>
<th>Major Diam.</th>
<th>Minor Diam.</th>
<th>Axis</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>4.75</td>
<td>15.0 mm.</td>
<td>11 mm.</td>
<td>6.5 mm.</td>
</tr>
<tr>
<td>Variety</td>
<td>5.25</td>
<td>17.5</td>
<td>14</td>
<td>6.0</td>
</tr>
</tbody>
</table>

Very similar specimens were obtained from Anticosti Island and from Marl Lake, Michigan, in which the coil is even more irregularly wound, a condition I take to be pathological. The most noticeable difference, after the axially shorter whorls and larger size, is in the umbilicus, which in the variety is, as it were, reamed out, exhibiting three and a half whorls; while in the more compact type the umbilicus when examined with a lens shows only two and a half whorls, which
diminish in size much more rapidly than in the variety. The campanulate aperture is about the same size in both forms, but seems larger in the type because the rest of the shell is so much more tightly wound. The suture on the apical side seems deeper and wider than in the type. Nine specimens of the variety were obtained, and I suggest for it the name *rudentis*, from the similarity of the whorls to a coiled hawser.

**Planorbis (Menetus) exacuous** Say.

*Paludina hyalina* Lea, 1839 (scalariform monstrous).

**Range.** — Northern United States, east of the Rockies; Canada, etc., south to New Mexico.

Lake Superior to Lake Winnipeg! Manitoba generally; Moose Factory, Hudson Bay! Left bank of the Yukon below Fort Yukon, Alaska, in Pleistocene marl (A. J. Collier)!

**Variety megas** Dall, nov.: Bittle, Manitoba (R. M. Christy).

This species has a number of varieties both in size and form. The typical shell is of a pale brownish horn color, with a somewhat glistening surface, rather rudely striated by the incremental lines, and with faint, almost microscopic, revolving striae. The form is lenticular, coming to an acute angle at the periphery. In 1863 I found in the vicinity of Marquette, Michigan, an unusually depressed brownish variety in which the peripheral keel was delicately serrate. In the northwestern part of its range the tendency is for the species to become whitish and of a larger size than the average New York or New England specimens. This reaches its maximum in specimens collected in Manitoba by Mr. R. Miller Christy, for which I propose the varietal name *megas*. The comparative measurements are as follows:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type.</td>
<td>3.33</td>
<td>4.7 mm.</td>
<td>3.7 mm.</td>
<td>1.0 mm.</td>
</tr>
<tr>
<td>Variety.</td>
<td>3.75</td>
<td>7.8</td>
<td>6.0</td>
<td>2.0</td>
</tr>
</tbody>
</table>

The variety is of a slightly milky translucency; on the base the whorl is more or less impressed within the peripheral keel and the spiral striation is much more marked than in the typical form.

Binney has united with this species *Planorbis lens* Lea, 1839 (not Bronnniart, 1810) = *P. lenticularis* Lea, 1844 (not Schlotheim, 1818) = *P. brongniartiana* Lea, 1842; but an examination of Lea's
cotypes, now in the National Museum, makes it evident that Dr. Gould was right in referring this form to _P. dilatatus_ Gould, 1841 (not Pfeiffer, 1841¹), or _dilatus_ Haldeman, 1844. To this latter form, in my opinion, should be united, as local races, _P. buchanensis_ Lea, 1844, and _P. alabamensis_ Pilsbry. The young of _P. exacuous_ Say frequently approach _dilatatus_, but the latter can usually be distinguished by its axial height being greater, its columella more vertical, and the substance of the shell, especially in southern specimens, more thick and solid. The aperture of the adult _dilatatus_ is usually distinctly thickened by a deposit of callus, but in _exacuous_ I have never observed more than a very thin wash of shelly matter around the opening. I have spelled the name of this species as Say did in two separate works; as he gave no derivation it seems to me we have no right to correct his spelling on purely theoretical grounds.

**Planorbis (Menetus) opercularis** Gould.

_Planorbis opercularis_ var. _oregonensis_ Vanatta, Nautilus, ix, p. 53, Sept., 1895; not _P. oregonensis_ Tryon, 1865.

_Planorbis callioglyptus_ Vanatta, Nautilus, ix, p. 54, 1895.

_Range._—San Francisco and northward, west of the Sierra Nevada.

_Type form._ California! Oregon! Washington near Seattle!

_Variety centervillensis._ Tryon: Alameda, Calif. ! Noyo River, Calif. ! San Leandro, Calif. ! Oregon; Unalaska Island, Alaska !

_Variety oregonensis._ Vanatta: Salem and Portland, Oregon !

¹I learn through Prof. von Martens that Pfeiffer's species was published in the double part v-vi, of the Archiv für Naturgeschichte, either in the last part of 1841 or the early portion of 1842, so that Gould's priority is certain.
FAMILY LYMNAEIDÆ

This species is the analogue of *P. exacuous* Say on the Pacific Coast. The typical form from the Sacramento River and the vicinity of San Francisco Bay is quite lenticular, with the periphery marked by a (frequently margined) keel. The shell itself is pale yellow or white under a rather strong periostracum, which is almost invariably more or less discolored by deposits of a brown or black color. The sculpture is like that of *exacuous*, the spiral sculpture being faint and sometimes absent in southern specimens, and tending to be emphasized in northern ones. As a rule the margin of the aperture is not thickened except in young specimens which have been overtaken by drought or winter before maturity. The keel is generally, but not always, present in southern shells, but those from Oregon and northward show a tendency to form a shell either without a noticeable keel, or with the keel forming a margin to a plane upper surface, rather than a median carina. When compared with Cooper's types in the National Museum Mr. Vanatta's *P. callioglyptus* is seen to be identical. The variety *oregonensis* retains the typical form but has stronger spiral sculpture. I regard *P. centervillensis* of Tryon as a *P. planulatus* with the keel obsolete. What appear to be intergradational forms are numerous in the large series of the National Museum; though it would seem incredible to any one possessing only the extremes that they can belong to the same species.

*Planorbid* (Gyrnus) *hirsutus* Gould.

Northern Sweden.

This species appears to be common only in New England, if one may trust reports, and it is remarkable how few records there are of it in the literature of American fresh water shells.

The shell is variable in form; from having, in what I have regarded as the type, well rounded nearly cylindrical whorls, it varies to a form more or less depressed and carinate and with an oblique aper-
tured, which, when it has lost its hispid periostracum, can hardly be
distinguished from the shell which is usually called *deflectus* of Say. 
This latter form, which, when in perfect condition, is fully as hairy 
as the typical *hirsutus*, is apparently identical with the shell 
which European writers catalogue under the name *draparnaudi* 
or *draparnaldi* of Sheppard. In its best state this has a peripheral 
fringe of longer hairs than those elsewhere on the surface, beneath 
which is usually, but not always, a faint peripheral keel like that of 
*P. deflectus* Say, which is distinguishable, so far as the shell is 
concerned, only by its less profuse and hairy periostracum. I should not 
be at all surprised if the two were eventually shown to be extremes of 
one specific form, especially as I have been unable to find specimens of 
typical *deflectus* which do not somewhere exhibit traces of spiral striation 
like that of *P. hirsutus*. The identity of our American species 
with the so-called *P. albus* Müller, of Europe, I do not doubt, but 
whether the name *albus* is the proper one to use for the latter is open 
to question, and on the present occasion I prefer to use a name about 
whose application no doubt can exist. The differences which have 
been reported to exist between the New England and the European 
shell are due to the comparison being made between discrepant varieties. 
If a series including all varieties from many different localities in 
Europe, be compared with a similar American series, parallels for 
each variation will be found.

*Planorbis borealis* (Lovén MS.) Westerlund, after specimens fur- 
nished by Westerlund, is merely a somewhat delicately sculptured 
mutation of this species.

**Planorbis** (*Gyraulus*) *deflectus* Say.

*Planorbis deflectus* Say, Long's Exp. Rep., ii, p. 261, pl. xv, fig. 8, 1824.—
HaldeMan, Mon. Limn., p. 25, pl. iv, figs. 4-7, 1844 
(N. W. Territory).

*Planorbis virens* Adams, 1840; young shell.

*Planorbis obliquus* De Kay, 1843.

**FIG. 74. Planorbis deflectus** Say, 4.

Range.—In America the same as that of *P. hirsutus*.

Ottawa, Canada! Lake of the Woods! Great Slave 
Lake! Dall River, Alaska, Lat. 66° N. 1 Popof Island, 
Shumagins, Alaska (Kincaid)!

Doubtfully distinct from the preceding species. It differs chiefly 
from the variety *draparnaudi* by the feebleness or absence of the 
hispidity of the periostracum. The deflection of the aperture and the 
consequent form of the mouth of the shell are inconstant characters,
although they have been called ‘characteristic’ by the very authors whose evidence shows the inconstancy.

**Planorbis (Torquis) parvus** Say.

*Planorbis concavus* Anthony, MS., various catalogues.

*Planorbis billingsi* Lea, 1866, from types (Ottawa, Canada).

**Range.** — In America, the whole of eastern North America from Florida to N. Lat. 67°, and the Yukon drainage system.

Ottawa, Canada! northward and westward to Lake Winnipeg! the Saskatchewan River! Alberta at Laggan, Olds and McLeod; Manitoba at Brandon and Birtle! Methy Lake; Moose Factory! Fort Simpson, Mackenzie River! Lake Bennett, Yukon Territory! Left bank of the Yukon below Fort Yukon, Alaska! The most striking characteristic of this widespread species is its ‘reamed out’ umbilicus. *P. limophilus* Westerlund, its nearest European analogue, may be distinguished at once by its shallow and flattish umbilicus. It rarely shows any trace of spiral sculpture and, when clean, is brightly polished. In the last whorl of the adult the portion above the periphery is usually somewhat flattened or obliquely depressed.

**Planorbis (Torquis) vermicularis** Gould.

**Range.** — Northern California! Oregon! and Vancouver Island, British Columbia!

On comparison, the type of *P. vermicularis* is seen to have vertically deeper whorls than a specimen of *P. parvus* of the same number and diameter. The aperture is more expanded, and much larger, as one would expect from the greater lumen of the whorl. Specimens from middle and southern California have a different aspect and may prove on more careful study to belong to *P. parvus*. They certainly do not agree with the Oregon shell, which, however, I have seen from Noyo, California.
Planorbis (Torquis) nathorsti Westerlund.

Aulatsivik, West Greenland (Sofia Expedition); Labrador (Storer). This species is said to approach *P. arcticus*, but has four and a half turns in a diameter of 3.5 mm., while the latter turns only three and a half times in 5.0 mm. *P. nathorsti* has spiral as well as transverse striation. It has not been figured.

Some specimens in the National Museum collected in Labrador exhibit about four turns in 3.5 mm. diameter, according to my calculation, but so much personal equation enters into the estimation of the extent of the first whorl that I am inclined to think they belong to Westerlund's species, in which case it is intermediate between *parvus* and *arcticus*, but without the excavated umbilicus of the former.

Planorbis (Torquis) arcticus Möller.

Species with larger whorls, the last more expanded near the aperture, and with the sides of the umbilicus not excavated as in *P. parvus* Say.

Planorbis (Torquis) umbilicatellus Cockerell.

**Range.**—From Mesilla, New Mexico! northward, through Colorado, Montana, Iowa, Minnesota, to Manitoba.

Rapid City, Birtle, Brandon! in Manitoba; McLeod, Red Deer, Olds, Laggan, in Alberta.

Planorbis (Armiger) crista Linné.

**Range.**—Planorbis costatus De Tar and Beecher, leaflet of one page, Albany, Oct. 25, 1878.

Range. — Europe, Algeria, in the Old World; in America at Caribou, Aroostook Co., Maine! Hamilton and Ottawa, Canada; Ann Arbor, Michigan! Red Deer in Alberta; Manitoba.

This small and inconspicuous species will doubtless be found in many other localities when thorough search is made.

Genus Segmentina Fleming.

Discus Haldeman, Mon. Limn., i, p. 4 of cover, July, 1840 (P. armigerus Say), not of Fitzinger, 1833.

This genus was founded by Fleming on the Planorbis nitidus of Müller, of which lacustris Lightfoot, is a synonym. I have not been able to verify the reference to the Edinburgh Encyclopaedia. Leach’s name was circulated in proof sheets, but not actually published or cited by other authors until after Fleming’s description appeared. Beck called a group of Planorbis ‘Dentati’ but applied no name to the group, and the transformation by Gray to ‘Dentatus,’ as if it had been intended for a generic or subgeneric name, seems quite unwarranted.

The genus may be divided into three groups as follows:

Subgenus Segmentina s. s. Base flattened, coil close, margin of the aperture simple, sharp; lamellae ridgelike, several sets persistent in the adult. Type P. nitidus Müller. Palearctic region.

Subgenus Planorbula Haldeman. Whorls rounded, coil loose, margin of the aperture simple, sharp, slightly expanded; lamellae dentiform, only one set persistent in the adult. Type, P. armigerus Say. Nearctic region.

Haldemanina Dall, n. sect., whorls carinate above and below, margin of aperture thickened and reflected; lamellae complex, dentiform and ridgelike, one series persistent in the adult. Type, Planorbis wheatleyi Lea. Coosa drainage of Alabama.
The lamellation of *Segmentina* is composed of irregular undulate ridges, radiating from the axis of the shell. In *Planorbula* there are four dentiform lamellae on the outer and two (one quite small) on the axial side of the throat, in a general way mostly turned in the direction of the coil, and the earlier series are absorbed as the animal grows. The position and shape of these lamellae are remarkably uniform in all the species. In *Haldemanina* the lamellae are more elongate and complex, requiring a diagram to define their relations, but on the whole more like *Planorbula* than *Segmentina*. (See Binney, Land and Fw. Sh. N. Am., ii, p. 137, figs. 226—7, 1865.)

*Segmentina (Planorbula) armigera* Say.

*Planorbis armiger* Beck, Index, p. 123, 1838.

Range. — New England and the Middle States, south to Georgia, westward to Nebraska, and northward to Great Slave Lake.

Lake Winnipeg and the Saskatchewan River! Egg Lake, Saskatchewan: Red Deer· Battle River; Great Playgreen Lake, Manitoba; Fort Ellice and Fort Pelly; Vermilion Lake; Moose Factory; James Bay! Fort Resolution, Great Slave Lake!

Fig. 76. *Planorbula armigera* Say. of *P. wheatleyi* Lea, for comparison.

Fig. 77. Teeth magnified.

Shell biconcave, of five whorls, polished, with an olivaceous periostracum; upper surface slightly concave in the center, the suture deep but not channelled, upper surface of the whorls with an obscure carination, the last part of the last whorl expanded and suddenly deflected downward, base with a steeply funicular umbilicus, exhibiting in scalar fashion all the whorls, and bordered by an obtuse carina; periphery of the whorls median, rounded; lip simple, hardly thickened, continued across the body by a thin callus; aperture at an angle of 45° to the vertical axis; surface sculptured by fine lines of growth and obsolete microscopic, inconstant, spiral striation. Max. diam. 8.0; min. diam. 6.5; height 3.0 mm.

This common species extends well to the north, but has not yet been reported from any part of the Pacific drainage, where it appears to be replaced by a very similar species, *P. declivis* Tate, which however has not yet been collected north of the Umpqua River, Oregon, specimens from that locality and from Nicaragua being in the National Museum.
Segmentina (Planorbula) christyi n. sp. Plate ii, figs. 10, 11.

Shell resembling P. armigera in a general way but having six whorls, the upper surface nearly flat, the latter part of the last whorl in nearly the same plane as the preceding whorls, with no marked deflection; the whorls rounded, with no carina above or below; the surface sculptured with fine close silky incremental lines and fine sharp spiral striae, giving a minutely reticulate effect when magnified; aperture-plane about 25° from the vertical; teeth very similar in form and position to those of P. armigera. Max. diam. 10.0; min. diam. 7.5; height 3.0 mm.

High Bluff, Manitoba! (R. Miller Christy); Fort Smith, Mackenzie River! (E. A. Preble).

After comparing these shells with a large series of P. armigera and finding nothing intermediate, I conclude that this form is worthy of a name. I have examined seven specimens of P. christyi, and several hundred from forty different localities, north and south, of P. armigera. The present form is the largest, flattest, and most sharply sculptured of the group.

Family PHYSIDÆ.

Genus Physa Draparnaud.

Enydra Hübner, Zwei Briefe, 1810 (nomenclature non-Linnean?).

Physella Haldeeman, Mon. Limn., i, pp. 14, 38, 1842; type P. globosa Hald.—Dall, op. cit., p. 355, 1870.

This genus has suffered from its resemblance to the sinistral Lymnaeas and the physiform Planorboimds, which have been and still are frequently confounded with the true Physas. Not until much more is known of the dentition and soft parts will it be practicable to eliminate from Physa all the unrelated species. The group containing Isidora, Physopsis, etc., is chiefly South European and African, but it is probable that some of the subtropical American species also belong to it. The subgenus Physella Haldeman, was proposed because the author believed it to be branchiate instead of pulmonate, but we now know that undoubted species of Lymnaea, having no access to the atmosphere, live in the deep waters of some of the Swiss lakes, perhaps gathering up globules of oxygen freed by aquatic plants; and unless some more definite observations show anatomical distinctions (such as were merely surmised by Haldeman) the group is hardly worth retention. Physodon Haldeman, so far as the shell is concerned, differs from Physa s. s. only by an almost imperceptible thickening below the obscure plait on the pillar, and, in default of other characters, might well be dispensed with.

The soft parts of Diastropha contorta (Mich.) have not been described, and there is some reason to think it may be an Isidora. Gray, who first introduced it in connection with the above mentioned species, subsequently listed it as a name (MS.?) given by Guilding, and mentioned as type Physa guildingi Swainson, which is an Aplexa.

The groups into which the genus may confidently be divided are as follows:

Section Physa s. s. Shell sinistral, ovoid, polished, with a spire shorter than the length of the aperture, an obscure plait on the pillar, with the pillar merging gradually into the peristome, the outer lip sharp, often with a slight thickening internally, the inner lip closely appressed to the body and pillar, a very small or no umbilicus, the surface of the shell smooth or microscopically striated. Type Bulla fontinalis Linné. Holarctic and Temperate regions of both hemispheres, also Hawaii.
Section *Macrophysa* Meek. Shell elongate, columnar, large, the last whorl and aperture small compared with that of the typical *Physa*, the surface axially striated. Type *Physa columnaris* Deshayes, Eocene of Paris Basin.

Section *Costatella* Dall. Shell physiform, polished, sculptured with axial ribs. Type *Physa costata* Newcomb.

The section *Macrophysa* has been affiliated to *Isidora* by Sandberger and others, but as the species is only known in the fossil state some doubt must remain as to its relations. It has somewhat the form of *Isidora wahlbergi* Krauss from South Africa, but the resemblance may be merely a parallelism and not an indication of relationship, as we find several species of *Isidora* absolutely indistinguishable from true *Physa* except by anatomical examination.

The groups known as *Ameria* Adams, *Glyptophysa* Crosse, *Plesiophysa* Crosse and Fischer, *Physopsis* Krauss, *Pulmobranchia* Pelseneer, etc., are more or less intimately connected with *Isidora* Ehrenberg (*Bulinus* Adanson) and do not form part of the family *Physidæ*. None of them occurs in the region to which this paper relates. I am indebted to the discussion of American Physae by O. A. Crandall in the Nautilus, volume xv, for assistance in determining the species of *Physa* from the north.

**Physa heterostropha** Say.

*Physa heterostropha* Say, Nicholson's Encycl., Am. ed. (no pagination), pl. 1, fig. 6, 1817. — Haldeman, Mon. Limn., p. 23, pl. 11, figs. 1–9, 1843.

—Binney, Land and Fw. Sh. N. Am., ii, p. 84, figs. 144–5, 1865.

*Physa plicata* de Kay, *fragilis* Mighels, *lata* Tryon, *primeana* Tryon, and *philippii* Küster, are said to be synonymous by Crandall.

**Range.** — From the Potomac and Ohio Rivers northward, and westward to the Mississippi.

Readily recognizable by its form and the absence of microscopic spiral sculpture. The northern specimens, when dead, are of a beautiful opalescent white with a claret colored apex.

**Physa gyrina** Say.

Physa hildrethiana Lea, *oleacea* Tryon, and *albofusata* Ancy, are united by Crandall with this species.  

*Physa fontinalis* J. DE C. SOWERBY (in Richardson), not of Linné.

**Range.**—The United States east of the Mississippi, Canada, and northward.

Manitoba! Lower Saskatchewan near Lake Winnipeg! York Factory, Keewatin; Great Slave Lake! Methy Lake to Great Bear Lake (Richardson).

Variety *oleacea* Tryon, also variety *hildrethiana* Lea: Great Slave Lake; Port Clarence, Alaska (Bean).

This is the prevalent species over the north country, extending to the Arctic Circle at Great Bear Lake, and westward to Bering Strait. It is to be noted however that *Physa* in this region is nowhere a common form like *Lymnaea* or *Planorbis*, or even *Aplexa*. The varieties noted differ from one another and from the typical form chiefly in the character of slenderness.

**Physa ancillaria** Say.

*Physa vinosa* GOULD, and *P. crassa* WALKER, are regarded as subspecies of *P. ancillaria* by Crandall, and Binney unites with it *P. obesa* De Kay.

**Range.**—The United States northward from the Potomac and Ohio Rivers, and east of the Mississippi, to the Saskatchewan. Variety *vinosa* Gould, Lake Superior.

Manitoba. Lake of the Woods; Lake Winnipeg; and the lower Saskatchewan River.

The above localities are cited from the literature; I have seen no specimens from north of the United States, west of Ontario.

**Physa lordi** Baird.

**Range.**—Washington and British Columbia, east of the Cascade Mountains, eastward to the northern peninsula of Michigan, and southward at high altitudes to New Mexico.

Round Lake! Lake Houghton! and Lake Douglas! northern Michigan! Mingusville, Montana! Ft. Col-
ville, Wash. Lake Osoyoos, Lat. 49° and Kootenai Lake, British Columbia; San Rafael, Valencia Co., New Mexico; altitude 6,000 feet!

I find this remarkable species in the National collection labelled *P. parkeri* Currier. There is a form very similar in miniature to this, which occurs in the Gila River, Arizona, and elsewhere in that region, but, while this may be a dwarf form of *P. lordi*, I do not feel sufficiently certain to include it in the range of the latter. The Michigan specimens however are typical, and finely developed, not in any way to be distinguished from those collected in Washington.

**Physa propinqua** Tryon.

Range. — Jordan Creek, SW. Idaho, west to Puget Sound and south to Los Angeles, Calif.

Puget Sound drainage! Sumas Prairie, Fraser River valley, British Columbia, and elsewhere in the lowlands of British Columbia, east of the Cascades.

This form closely resembles *P. heterostropha* Say, and is the shell which has been listed by that name from the Pacific Coast, where according to Tryon and Crandall the true *P. heterostropha* does not occur. Whether it is a distinct species, or a special mutation of *P. ampullacea* Gould, or a western race of some other species, I do not feel able to determine, and so I accept Tryon's assurance that it is a valid species.

**Physa ampullacea** Gould.

Range. — Oregon and Washington, northward to Norton Sound on the Pacific Coast.

Oregon! Lake Oyosa, Washington! Vancouver Island, near Victoria; ponds near St. Michael, Norton Sound, Alaska, rare!

A single specimen of what seems to be this species was found among other shells collected near St. Michael, Alaska, by E. W. Nelson.

**Physa (Aplexa?) hordacea** Lea.

Genus *Aplexa* Fleming.

*Turbo* (sp.) WALKER, Test. Min. var., p. 15, 1787.

*Bulinus* O. T. MÜLLER, in Der Naturforscher (Halle), xv, p. 6, 1781 (after Adanson, Sénégal, p. 5, 1757, non binomial).

*Bulinus* POIRET, Coq. Fluv. et Terr., p. 41, 1801 ; not of Scopoli.

*Physa* FITZINGER, Syst. Verz., p. 110, 1833 ; not of Draparnda.

*Nauta* BECK (in syn.), Ind. Moll., p. 166, 1838.

*Nauta* WESTERLUND, Fauna Pal. Reg., v, p. 57, 1885.

Shells of species allied to *Physa*, but usually more slender and elevated, the mantle not extending beyond the margin of the aperture and its edge entire, without filamentary appendages; jaw strongly

**Range.** — Oregon, Washington, Vancouver Island.

Fort Vancouver, Wash. ! near Puget Sound, Wash. !

This is the small species, having much the appearance of an *Aplexa*, which has been cited on the authority of Dr. J. G. Cooper as *Aplexa hypnorum* from near Puget Sound. This error was afterward corrected by Cooper himself. No observations have been recorded in regard to the animal, and when these have been made it is entirely possible that the creature may turn out to be an *Aplexa*. It is entirely distinct from *A. hypnorum* at any rate
arcuated, thin, cartilaginous, without accessory plates; other characters as in *Physa*.

Type *Bulla hypnorum* Linné, 1758, Holarctic.

The nomenclature of this genus has been subject to some vicissitudes. In 1757 Adanson, who did not adopt the binomial nomenclature, described a minute shell from the fresh waters of Senegal under the name of "le Bulin, *Bulinus*." From its form and size it was certainly not an *Aplexa*, but rather a species of the group called by Ehrenberg, in 1831, *Isidora*. This genus has the jaw and radula of a *Planorbis* and may be regarded as a physiform relation of the latter genus. To a considerable extent it replaces *Physa* in tropical Africa.

Scopoli in 1777 attempted to utilize Adanson’s researches, and proposed a genus *Bulinus* in which he included *Limnea, Succinea* and *Bythinia* (sp.), attributing the genus to Adanson and paraphrasing Adanson’s diagnosis of the characters of the animal. The name was later used for the large land shells for which it is familiar, but to which the diagnosis cannot be applied.

It seems almost certain that *Bulinus* (Scopoli) is a misprint for *Bulinus* (Adanson), but, as usual, several authors have not hesitated to propose a bogus derivation for a name for which the author gave no derivation, and have ignored the statement of Adanson, who gives a legitimate and totally different source for the name.

However this may be, *Bulinus* long had currency in conchological nomenclature for animals with which we are not here concerned, and in 1781 Otho Friedrich Müller revived Adanson’s name in its original form for the group named *Physa* by Draparnaud twenty years later. Müller included in his list of species Adanson’s type (to which he gave the binomial name *Bulinus senegalensis*), *Bulinus turritus* (= *Aplexa hypnorum* L. sp.) and *Bulinus perla* (= *Physa fontinalis* Drap.).

Since he states that his genus is that of Adanson, it follows that Adanson’s sole species must be taken as the type, which eliminates one of the three groups concerned. For the group represented by *Physa fontinalis* Draparnaud’s name has been generally and properly retained, while the first available name for the third group is *Aplexa* Fleming. This is accepted and defined by Sowerby as indicated in the synonymy above given, but may have been used earlier in print by Fleming; though I have found no record of it if this be the case. Sowerby speaks of it as if it were not a manuscript name, but does not explicitly so state.
Later on Herrmannsen supplies a gratuitous derivation for Fleming's name and, because it does not properly conform to his imaginary source, alters the spelling to Aplecta.

This was totally unauthorized. Since no derivation was given by Sowerby, we are at liberty to regard the word as an arbitrary combination of letters formed on the analogy of *tripllex* and similar Latin words, but we are not at liberty to manufacture an imaginary derivation and then force the name to conform to it.

Several authors divided Müller's group differently, and several synonyms were proposed for parts of it, as will be evident on a study of the synonymy.

The genus occurs in the Tertiary of Europe and North America, and possibly as far back as the Middle Cretaceous of North America. Several well characterized forms have been described from the Laramie. The type is known from the Palearctic and Nearctic regions, and the genus extends south to Mexico, where in the tropical conditions of Mazatlan perhaps the finest of the recent species occurs abundantly. In Alaska and on the adjacent continent of Asia but one species is known, the type.

**Aplexa hypnorum** (Linné).

*Bullimus hypnorum* Bruguère, Encycl. Mèth., p. 301, 1792.

*Physa hypnorum* Draparnaud, Hist., p. 55, pl. III, figs. 12-13, 1805.—Haldeman, Mon. Limn., p. 36, pl. V, figs. 4-9, 1842.—Forbes and Hanley, Brit. Moll., iv, p. 143, pl. cxxii, figs. 6-7.

*Bulla turrita* Gmelin, Syst. Nat., VI, p. 3428, No. 20, 1792.

*Turbo stagnalis* Walker, Test. Min. Rar., p. 15, pl. II, fig. 54, 1787.

Aplexus hypnorum Chenu, Man. de Conch., 1, p. 481, fig. 3556, 1859.
Physa (Nauta) hypnorum Linné.—Westerlund, Fauna Palaarct., Reg. v, p. 57, 1885.
Physa (Nauta) hypnorum var. polaris Westerlund, op. cit., p. 58.

Range.—Northern Europe, Asia and America, Northern United States and Canada.

Snake River, Idaho! Middle Park, Colorado! Upper Missouri in Montana! Utah (Hemphill)! This well known species is supposed to be circumboreal, but there are some peculiarities in its known distribution. While it extends to northern and western Alaska and down into the mountainous region in Colorado and Utah, it has not been reported so far, authentically, from west of the Cascades, either in the United States or British Columbia. There was one record "near Puget Sound" by Dr. J. G. Cooper, which is cited by W. Cooper and Carpenter, but this refers to a shell obtained at Vancouver, Wash. (not Vancouver Island); by Sir George Simpson, which was afterward described by Dr. Lea as Physa hordeacea. It is not positively known that this species is not a Physa, though Tryon has referred it to Bulinus (= Aplexa), on the strength of its general aspect.

A number of varieties have been proposed, but there is not much systematic basis for such of these mutations as I have seen.

Genus Ancylus Müller.

Subgenus Ancylus s. s.

Patella (sp.) Linné, Syst. Nat., ed. x, p. 783, 1758.

Ancylus Graells, Cat. Moll. España, p. 22, 1846; err. typ.?

> Haldemania Clessin, 1880, not of Tryon, 1862.

Subgenus Acroloxus Beck.

Acroloxus Bourguignat, J. de Conchyl., iv, p. 169, 1853; a modification of Acroloxus Beck.

Subgenus Ancylastraum Bourguignat.

> Subgenus Gundlachia Pfeiffer.

The genus Ancylus cannot be cited as of Geoffroy, first, because that author did not adopt the Linnean nomenclature, and secondly, because his only species was identified by him with Patella lacustris L., which is the type of Acroloxus, and, though Bourguignat and
others have tried to propagate the view that Geoffroy’s species was the 
A. fluviatilis, their arguments cannot be said to outweigh the positive 
statement of the original author. The first binomial author to use 
Ancylus was Müller, who must be credited with the genus. The name 
Ancylastrum, published by Bourguignat (though probably suggested 
by Moquin Tandon) was doubtless intended to be the equivalent of 
Ancylus s. s., but the publishing author distinctly and repeatedly 
announced the type to be Ancylus cumingianus, which differs in 
many respects from typical Ancylus, and will therefore retain the name, 
which otherwise would have fallen into the synonymy of Ancylus s. s. 
Acroloxus Beck, typified by A. lacustris Müller, seems to be a well 
characterized subdivision. Beck’s first species was examined by Gray 
and determined to be a Velletia, which is an exact synonym of Acro-
loxus. Protancylus was proposed by the Sarasin brothers in 1898, 
for a form resembling Ancylus, from Celebes, but in which the gill is 
fully developed.

Typical Ancylus seems to be an Old World form, but Acroloxus is 
represented in both hemispheres. The subdivisions of the typical sub-
genus so far recognized are as follows:

*Bordelia* Bourguignat, Rev. de Zool, p. 13, 1862; Spic. Mal., 
xcv, Jan., 1862, type *B. drouetiana* Bourg., Algeria.

This form, which is said to be an air-breather, a fact needing con-
firmation, is radiately ribbed and has a sinistral apex. More informa-
tion about it is much needed, and it may prove to be an Acroloxus.

*Lanx* Clessin, Conch. Cab., ed. 11, pt. 299, p. 10, 1880; type *A. new-
berryi* Lea, Oregon and California.

The type has a smooth or concentrically striated apex, subcentrally 
situated, obtuse; the shell is larger and more solid than the majority of 
the genus. *A. patelloides* Lea, placed by Clessin with the above, 
has a shell like *A. newberryi*, but more delicate, depressed, and with 
a well marked radial system of coloration.

The following groups are Nearctic or American; *Ferrissia* is also 
South African.

*Laapex* Walker, Nautilus, xvii, June, 1903, p. 15; type *Ancylus 
fuscus* C. B. Adams. Chiefly lacustrine, with a smooth nepionic 
shell.

*Ferrissia* Walker, op. cit., p. 15; type *Ancylus rivularis* Say. 
Chiefly fluviatile, with a radiately sculptured nepionic shell.

The question as to whether Gundlachia is a distinct genus or merely an 
exceptional second-season growth of *Ancylus*, has been discussed
by me in the paper cited in the synonymy, since publishing which I find Dr. J. G. Cooper had also expressed the same opinion in 1875.

_Ancylus (Ferrissia) rivularis_ Say.

_Ancylus rivularis_ Say, Journ. Acad. Nat. Sci., i, p. 124, 1817.— _Haldeman, Mon. Limn.,_ p. 4, pl. 1, fig. 1, 1844 (Delaware River).

_Range._—Northern United States east of the Mississippi, New Mexico, Canada, Manitoba.

Souris River, Manitoba, Dawson.

_Ancylus (Ferrissia) parallelus_ Haldeman.

_Ancylus parallelus_ Haldeman, Mon. Limn., pt. 2, p. 3 of cover, 1841 (Vermont); pt. 7, p. 11, pl. 1, fig. 6, 1844.— _Binney, Land and Fw. Sh. N. Am.,_ ii, p. 142, 1865.

_Range._—New England; Canada, Manitoba.

Pine Creek; Rainy River; and Lake of the Woods, in Manitoba.

_Ancylus (Laevapex) fragilis_ Tryon.

Black River, Puget Sound.

_Range._—California; Puget Sound drainage (caurinus), Vancouver Island near Victoria! (caurinus).

Tryon unites these under his prior name. The Vancouver specimens are certainly identical with Cooper's shell.

_Fig. 82. Ancylus kootaniensis_ Baird.

_Ancylus (Laevapex) kootaniensis_ Baird.

_Range._—Kootenai and Spokane Rivers, British Columbia.
Family Siphonariidae.

Genus Siphonaria Sowerby.

*Trimusculus* (Schmidt, MS.) Möller, Isis, 1832, p. 132.

? *Liria* Gray, Phil. Mag. and Journ., LXIII, p. 275, April, 1824.

The type of *Liria* is *Le Liri* Adanson, Sénégal, p. 32, pl. 2, fig. 2, 1757; stated by Gray to be a synonym of Sowerby's genus, but it is probable that Adanson's shell is not a *Siphonaria*.

Subgenus *Siphonaria* s. s.

*Siphonaria* Dall, Am. Journ. Conch., vi, p. 31, 1870.

Shell solid, porcellanous, with subcentral apex and radial sculpture; inner lateral teeth of the radula bifid, outer trifid. Habitat, tropical or warmer seas. Type, *S. sipho* Sowerby.

Subgenus *Liriola* Dall.

Shell thin, horny, with apex eccentric; smooth or faintly radially striate. Habitat, cooler or temperate seas. Type *S. thersites* Carpenter.

*Siphonaria* (*Liriola*) *thersites* Carpenter.

*Siphonaria (Liriola) thersites* Dall, Am. Journ. Conch., vi, pp. 32, 33, pl. iv, fig. 8, pl. v, figs. 2, 5, 1870.

Range. — Strait of Fuca to the Aleutian Islands, on stones near low water mark.

This is one of the most common and characteristic mollusks of the northwest coast. It lives between tidemarks, often where it must be submerged twenty out of twenty-four hours of the day, but is sometimes dredged in 20 fathoms, dead.
Family **ONCHIDIIDÆ**.

Genus *Onchidium* Buchanan, 1800.

Type *Onchidium typhæ* Buchanan, Trans. Linn. Soc., v, p. 132, 1800.

Subgenus *Onchidella* Gray, 1850.

Type *Onchidium nigricans* Quoy, Fig. Moll. An., iv, p. 117, pl. 181, fig. 1, 1850 (selected as type by Herrmannsen, Ind. Gen. Mal., Suppl., 1852).

Dorsal surface without arborescent processes, margin of the mantle with prominent spaced papillae, serving as conduits for mucous glands; lower surface of the mantle with muciparous glands; dorsum with dorsal eyes; mouth agnathous. Warmer seas.

Section **Arctonchis** Dall, nov.

Species small, like *Onchidella*, but without muciparous glands on the lower side of the mantle, without dorsal eyes and with a jaw. Cool temperate and boreal coasts.

Type *Onchidella borealis* Dall.

I had long since proposed to retain for this group the name *Onchidella*, supposing that name to be practically a synonym of *Onchidium*. This, however, is not now regarded as allowable, and *Onchidella* must follow the fate of its type.

I propose therefore the sectional name *Arctonchis* for the group of small boreal *Onchidella* which includes at least *O. borealis* and *O. celtica* Forbes and Hanley.

*Onchidella (Arctonchis) borealis* Dall.

**Range.** — California to Bering Sea on the N. W. coast of America. California (Binney); Coos Bay, Oregon (Hemphill); Victoria, Vancouver Island! Lituya Bay! Port Mulgrave! Port Etches! Unalaska! and Port Möller on Bering Sea! In Alaska.

Observations on this species have been published by the writer, Mr. W. G. Binney, Semper, and Henry Hemphill; and, as their articles are short and widely scattered in the literature, an abstract of the
whole, with additions, is now given so that the data in regard to this species may be obtained in one place.

The animal lives between tides, where at high water it is covered by the sea, usually on stones or projecting rocks, either where it is covered with *Fucus* or on the underside of stones which thus form a shelter. It seems to be gregarious in its habits, as many as fifty specimens having been taken from a single crevice in shaly rock. When in motion it moves quite rapidly for so small an animal, with two short stout tentacles tipped by keen black eyes protruding beyond the front edge of the mantle. The upper surface is dark slate color, with spots or streaks of light gray or whitish. It appears smooth, but as if having small round tubercles beneath the smooth skin, which when the animal is contracted in alcohol are much more conspicuous than in life. Around the edge of the mantle is a single row of larger and more prominent tubercles corresponding to an equal number of mucous glands. These, projecting, give the margin a serrate or fringed appearance. The animal, when in motion, is about twelve millimeters long, four and one half wide, and three millimeters high, oblong oval in form, a little wider behind than in front. When at rest in a contracted state it is nearly circular in form, a little longer than wide, the center of the dorsum elevated in a bluntly pointed manner, giving the creature much the aspect of a young *Acmeea*. The lower surface of the body is of a greenish white, and, when the animal is moving, the foot seems to undergo rapid undulation. The muzzle exhibits anterior ovate extensions separated by a sulcus in the median line, as in other species of the genus.

Neither *Onchidella borealis* nor *O. celtica* possesses the singular dorsal eyes characteristic of many tropical species.

*O. borealis* differs from *O. carpenteri* Binney, and all the other species of the family now known (except *O. celticum*), in possessing a thin delicate smooth jaw, the presence of which has been demonstrated by both Binney and Semper. According to Joyeaux Laffliue *O. celticum* also possesses a jaw, though the surface of the dorsum is, if the figure given by Forbes and Hanley be accurate, much more prominently tuberculous than in *O. borealis*. *O. carpenteri* Binney, a small species reported by Binney from California and Puget Sound, is according to that author agnathous, and therefore belongs to the typical section of the genus.

The dentition of *O. borealis* has been worked out by Binney and confirmed by Semper. The radula is long and wide, the teeth arranged strongly *en chevron*, with a formula of $\frac{s}{2} \cdot \frac{1}{2} \cdot \frac{s}{2}$. The rhachidian
tooth is large, longer than wide, truncated above, expanded below its middle, and incurved at the basal margin. The reflected portion is large, tricuspid, the cusps prominent. The laterals have a long, narrow base of attachment, a small portion of its upper part thrown outward, the rest curving inward, giving an irregular arcuate form to the base as a whole; the anterior and posterior margins of this base are abruptly truncate. The reflected part is rather posterior and carries a large, wide, expanding, bluntly truncated cusp on the outer side, and on the inner a very small conical cusp. The successive teeth laterally from the middle of the radula at first increase, then gradually decrease in size, but retain essentially the same characters to the outer termination of the row.

From the typical Onchidium (schrammi Bland and Binney, Guadeloupe, W. I.) the teeth differ by the wider rhachidian, with more nearly equal cusps, by the presence of two distinct cusps on the laterals, and by the curve of the lateral bases, which in O. schrammi have their posterior portions curved toward the center of the radula, while in O. borealis the curve is in the opposite direction. In Onchidella floridana Dall, an oculiferous agnathous species from Knight's Key, Florida, the discrepancy of the rhachidian cusps and the curve of the lateral bases agree with O. schrammi, but there is a small accessory inner cusp to the laterals.

Mr. Binney informs me that the liver in O. borealis is in fasciculi of long cæca, one on each side; there is also an accessory lateral pouch to the stomach, which also has a fasciculus of cæca, making three biliary ducts.

According to Semper this species agrees in most respects with the fifth of the groups into which he divides Onchidium. There is a single row of large glands which open through equally spaced small tubercles on the mantle edge. The other glands, which in the other species (except O. celtica) empty on the under surface of the mantle, are absent in this form. The penis is short and thick, consisting of two well marked portions. In the posterior thinner part a short broad penial papilla is present, at the base of which the spermatic duct opens. The wall of this part is marked by extremely shallow grooves in which concretions are present, very like those found in the deep grooves of other species. The spermatic cord is short and feebly twisted. The penial retractor muscle is thin and attached proximally to the middle of the pericardial sac on the inner surface of the foot. The jaw and radula are as described by Binney.

I should like here to record my dissent from the ingenious hypothesis
Family AURICULIDÆ

by which Semper associated the occurrence of dorsal eyes in Onchidium with the presence of the fish Periophthalmus. There are both oculiferous and (dorsally) blind species of Onchidium in the Galápagos, and an oculiferous species in Florida and Bermuda, and in neither of these regions is Periophthalmus known. It is of course not only necessary that an hypothesis should account for the facts, but that it also should be true, but the latter half of the proposition is only too liable to be left unverified.

Family AURICULIDÆ.

Genus Carychium Müller.

Helix (sp.) Gmelin, Syst. Nat., vi, p. 3665, 1792.

Auricula (sp.) Draparnaud, Tableau des Moll., p. 54, 1801; Hist., p. 57, pl. iii, figs. 18, 19, 1805.

Fig. 83. Carychium exiguum Say. Animal and shell magnified.

The species of this genus are so small that a special search almost is necessary to determine their presence or absence in a given locality.
So it is uncertain whether the range herein reported might not be considerably extended if thorough collecting had been done.

**Carychium exiguum** Say.

*Carychium exiguum* Pfeiffer, Wiegman's Archiv, 1, p. 224, 1841.—Binney, Land and Fw. Sh. N. Am., II, p. 6, figs. 5–9, 1865.

*Range.*—Temperate North America.

At Brandon, Pine Creek, and Carberry, Manitoba; Salt Spring Island, and at Comox, Vancouver Island, British Columbia.

**Carychium exile** Lea.

In the description of the animal of *Carychium* cited by Binney (under *C. exiguum*) and copied by Baker (Moll. Chicago Area, II, p. 254) the writer has confused the anterior end of the wide muzzle with the foot, although, by the figure adjacent to this paragraph, the relation of the parts is clearly shown. The foot of the animal is not "divided into two segments," but is entire, as required by the generic diagnosis.

**Family STREPOMATIDÆ.**

**Genus Pleurocera** Rafinesque.

*Pleurocera canaliculata* Say.

*Range.*—Ohio, Tennessee and Alabama, Indiana and Illinois.

This species is cited in J. de C. Sowerby's very inaccurate list, as coming from "Lake Superior to the Saskatchewan." No subsequent collector has confirmed this statement, which is doubtless entirely erroneous.

**Genus Goniobasis** Lea.

**Goniobasis plicifera** Lea, var. *silicula* Gould.

FAMILY AMNICOLIDÆ

Range.—Northern California, Oregon and Washington. Vancouver Island (Forbes)? British Columbia in streams west of the Cascades (Lord).

This species so much resembles the viviparous *Melania* of the Hawaiian Islands and the Orient, which has a fringed mantle edge, that for a long time it was doubted whether the little group of Pacific Coast species was not related to the oriental forms rather than to the *Goniobasis* of the eastern United States. An examination of the living animal by the writer a few years ago showed, however, that the Oregon species has a plain mantle edge and is oviparous, so that the resemblance referred to, though obvious, is probably merely the result of convergence, and expresses no intimate relationship.

Tryon regarded Gould's *silicula* as a species; others have thought it a variety of the older *plicifera*. Further studies are necessary to determine the question.

**Family AMNICOLIDÆ.**

*Amnicola limosa* Say.

*Amnicola limosa* Haldeman, Mon. Limn., p. 10, pl. i, figs. 5, 6, 1845. — Binney, Land and Fw. Sh. N. Am., iii, p. 84, fig. 166, 1865.

*Lyogyrus lehnerti* Ancey (Monstr.).

Range.—Virginia to Wisconsin and Hudson Bay. Lake Superior to the Height of Land; Athabaska at Lake La Loche (Richardson), N. Lat. 56° 30′; Lake of the Woods; Manitoba; Moose Factory, Hudson Bay! Big Sioux River, Nebraska! Salt Lake basin, Utah Lake! Utah.

This is the type of the genus, and it seems to reach the headwaters of the Atlantic and Hudson Bay drainage but not to reach the drainage on the other side of the watershed alluded to.

*Amnicola pallida* Haldeman.

Range.—New York northward to Canada and Manitoba. Lake Winnipeg, Brandon, and Pine Creek, Manitoba.
These northern localities are cited from the literature. I have seen no Manitoban specimens.

**Amnicola emarginata** Küster.

*Amnicola cincinnatiensis* Binney, Land and Fw. Sh. N. Am., iii, p. 85, fig. 169, 1865, not of Anthony?

**Range.** — Ohio and northward to Moose River, Hudson Bay.

Red River of the North; Manitoba; lower Saskatchewan, near Lake Winnipeg! Moose Factory! N. Lat. 51° on Hudson Bay.

More or less confusion has existed between the various shells which have carried the specific name *cincinnatiensis* in this family. The present species is the small shell with a flat planorboid apex which has usually been called *Bythinella obtusa* Lea. Baker, in his *Mollusks of the Chicago Area*, unites *cincinnatiensis* Binney with this species. It does not seem to me to resemble the *obtusa* of Lea, particularly.

**Amnicola cincinnatiensis** Anthony.

*Paludina cincinnatiensis* ANTHONY, Boston Journ. Nat. History, iii, p. 279, pl. iii, fig. 3, 1840.

*Amnicola (Cincinnatia) cincinnatiensis* BAKER, Moll. Chicago Area, ii, p. 325, pl. xxvi, fig. 14, 1902.

**Range.** — New York to Utah, Texas to Hudson Bay. Moose Factory, Hudson Bay!

The identity of the Hudson Bay specimens is apparently indubitable. The species is asserted by Pilsbry to occur in Texas and at various points in the basin of Great Salt Lake, Utah.

Genus **Lyogyrus** Gill.

**Lyogyrus granum** Say?

**Range.** — Virginia northward to the Great Lakes and Manitoba? Pennsylvania (Say). Pine Creek, Manitoba (Miller Christy).

Dr. Pilsbry, in the *Nautilus* (xi, No. 4, p. 42, 1898), says that the Canadian and northwestern specimens are not of the same species as
FAMILY AMNICOLIDÆ

Say's Pennsylvania type. The above range is taken from the literature; not having seen Manitoba specimens I am unable to determine what species they represent, but it appears that there is a small species in Manitoba resembling *L. granum*.

Genus **Fluminicola** Stimpson.

**Fluminicola nuttalliana** Lea.

**Range.** — California to British Columbia. Variety *hindsii* in Kootenai River and Wigwam River, at the foot of the Rocky Mountains, at an elevation up to 4,626 feet.

I have not seen any British Columbian specimens and accept the identity of *F. hindsii* and *nuttalliana* on Mr. Binney’s authority. According to Dr. Pilsbry this species is common to the Columbia River drainage of British Columbia and the United States.

**Fluminicola virens** Lea.

*Paludina nuclea* Lea, op. cit., p. 91, pl. xxiii, fig. 103, 1839.

**Range.** — Oregon, Willamette River, Washington, and Vancouver Island.

In this instance the Vancouver habitat is cited from the literature.

Genus **Pomatiopsis** Tryon.

**Pomatiopsis lapidaria** Say.

*Amnicola lapidaria* Haldeaman, Mon. Limn., viii, p. 18, pl. 1, fig. 10, 1845.

*Pomatiaopsis lustrica* Binney, Land and Fw. Sh. N. Am., III, p. 94, fig. 189, 1865, Cayuga Lake, N. Y.

**Range.** — Eastern North America from Georgia to Iowa and Hudson Bay.

Moose Factory, N. Lat. 51°, on Hudson Bay.

There is some doubt as to whether Say’s *lustrica* is the young of his *lapidaria* or not. I have followed the general usage in uniting them. If they should prove distinct it is, according to Mr. Binney, the *P. lustrica* which occurs in the Northwest and on the watershed south of Hudson Bay.

**Family VALVATIDÆ.**

Genus Valvata Müller.

*Gyrorbis* Fitzinger, Verz, p. 117, 1833; type ?? *cristata* Müller.

>*Valvata* Fitzinger, Verz, p. 117, 1833; type *V. cristata* (Müller).

*Volvata* Berge, Conch. Buch, pp. 17, 20, 26, 1847; *err. typ. ?*

*Cincinna* ‘Hübner,’ *fide* H. and A. Adams, op. cit., p. 343, 1854.

>*Valvata Schlüter,* op. cit., p. 13, 1854; *V. piscinalis* Fér.

This genus has been subdivided, according to the form of the shell, into the following sections, which appear, however, to have very little value.

*Valvata s. s.* (*Gyrorbis* Fitz.) Shell planorboid or depressed, without spiral keels. Type *V. cristata* Müller.

*Cincinna Mörch* (*Valvata Fitz.*). Shell turbinate, with a mod-
erate number of whorls slowly enlarging and without spiral keels. Type *V. piscinalis* ( Müller).

_Jelskia_ Bourguignat (_Jelskia_ West., not Tacz.). Shell turbinate, with few rapidly enlarging whorls and no spiral keels. Type *V. jelskii* Crosse.

_Tropidina_ H. and A. Adams. Shell depressed turbinate, with the upper surface of the spire more or less flattened and the whorls spirally keeled. Type *V. tricarinata* (Lesueur) Say.

Since Müller associated but one species with the genus when described, that species necessarily becomes the type. A failure to recognize this, when subdividing the genus, is responsible for several of the synonyms. I have not been able to consult Hübner's _Zwei Briefe_, and cite him on the authority of Westerlund, but, judging by his paper on _Cobresia_ of the same year, his nomenclature was not Linnean, although his artistic capacity seems to have been exceptional.

**Valvata tricarinata** Say.

*Valvata carinata* Sowerby, Genera, part xli, fig. 2, 1834.

*Valvata unicarinata* DeKay, _Zool. N. Y._, Moll., p. 118, pl. vi, fig. 129, 1843.

*Valvata tricarinata* var. _simplex_ Gould, Inv. Mass., p. 226, fig. 156 (right hand figure), 1841.

*Valvata tricarinata* var. _confusa_ Bryant Walker, _Nautilus_, xv, No. 11, p. 124, fig. 2, 1902.

**Range.** — From New England and Virginia westward to the Missouri, and northward.

Type: St. Lawrence River and the Great Lakes! Manitoba, in Great Playgreen and Winnipeg Lakes! and Pine Creek; Red Deer, Alberta; Moose Factory, Keewatin; Saskatchewan River! Great Slave Lake! Methy Lake in Lat. 57° N.

Full grown specimens of this species have three and a half whorls, a maximum diameter of 5, and an altitude of 3 mm. This applies to both varieties, though under exceptionally favorable circumstances it may be somewhat exceeded. The aperture is orbicular and almost vertical in plane.
Valvata sincera Say.

Range.—Northwest Territory (Bigsby, fide Say) southeast Keewatin in Attawapiskat and Kawingogs Rivers (McInnes) and the southwest point of Anticosti (McCann).

This shell, according to Say's original description and figure, is "sub-globose-conic" with "nearly four whorls," "finely and regularly wrinkled across," with a large umbilicus "exhibiting the volutions," and a diameter, at right angles to the axis, of slightly less than three millimeters, as engraved on the plate in Long's Expedition. I have not seen any shell corresponding to these characters from the northern United States, but Dr. Whiteaves has kindly sent me for examination some shells from southern Keewatin and Anticosti which may prove to be Say's *sincera*. In the literature and in collections we find the ecarinate *tricarinata (simplex* Gould) and all the non-carinated forms of the United States generally labelled ' *sincera* Say,' ' *simplex* Gould,' etc. Those specimens of *tricarinata* which preserve the 'subglobose' outline have an umbilicus smaller than the carinate shells instead of larger. The very flat and widely umbilicate form which is most generally labelled *sincera*, following Haldeman's figures, is much more like the *cristata* of Europe than it is like Say's shell. The specimens which have been called *sincera* in the literature of the region we are now interested in are, so far as I have been able to examine them, all of the next species.

The only shells in the National Museum which at all resemble Say's *sincera* are a series received from Aroostook County, Maine, collected by O. Nylander, which differ sufficiently to be called at least a very marked variety.

Valvata (*sincera* var.?) *nylanderi* nov.

Shell small, subglobose-conic, with four whorls of a pale greenish straw color; surface polished, with faint spiral striae, sculptured axially with thin, sharp, elevated, rather distant lamellae like those on *Zoögenites harpa* or *Planogyra asteriscus* Morse; these lamellae are closer and less elevated on the apical part of the shell; vertex, including most of the first two whorls, somewhat flattish or planorboid, after which the shell becomes subconic; the sutures deep; the base rounded, with a narrow but very deep umbilicus; plane of the aperture nearly vertical, the aperture orbicular, with simple sharp edges; the operculum multispiral, of the same color as the shell. Axial height 3.2 and 3.4; diameter 3.5 and 3.7; diameter of umbilicus .05 and
.07; of aperture 1.5 and 1.7 mm., in the broadest and narrowest specimens, respectively.

**Valvata lewisi** Currier.

*Valvata sincera* Haldeman (*pro parte*), Mon. Limn., VIII, pl. 1, figs. 6, 7, 8, 1845.

**Range.**—Northern United States from the Atlantic to the Pacific, and northward.

The name seems to have been originally proposed for a brown mutation of *V. sincera* Haldeman (*non* Say), but may well be extended to cover the whole species, which has no other available name. The shell when normally developed and adult has four whorls with a height of 3.6 and a diameter of 5.75 mm. It has a much wider umbilicus than var. *simplex* of *tricarinata* and is a larger shell, yet usually has a smaller protoconch. The sculpture is axial, fine and close, like the winding of thread on a spool. In the typical form this sculpture is coarser and more prominent than in the less common *helicoidea*. In both it is largely resident in the periostracum, the decorticated shell being nearly smooth.

**Valvata lewisi** var. *helicoidea* nov. Pl. II, figs. 1, 2.

This form resembles *lewisi* but is more depressed, almost flat above, and more or less flattened toward the suture; the whorls are more slender and near the aperture usually rather suddenly expanded; the surface is polished, the sculpture frequently obsolete, the umbilicus wide, and its bounding coil peripherally diverted during the growth of the last half whorl; height 2.5; of the aperture 2.0; diameter of shell 5.0 mm.

**Range.**—With the type form, to some extent everywhere, but especially toward the Northwest. Lake Bennett, Yukon Territory!
Old Fort Yukon, Alaska! thirty miles below Tanana on the Yukon River! Lake Lindeman; East Kootenai district, British Columbia.

This form is very close to *V. sibirica* Middendorff, which however has a more depressed apex and uniform fine sharp sculpture. *V. cristata* is of the same type, but much smaller.

**Valvata mergella** Westerlund.

*Range.*—Fort Clarence, near Bering Strait, Alaska (Vega); Popof Island, Shumagins, in small ponds (Kincaid); Stewart River, Yukon district (Canadian Geol. Survey).

This is the largest species of its group, measuring 5 mm. high and 7 mm. wide, with four whorls. The aperture is markedly expanded, the sculpture very fine and rather sharp. The protoconch in the Shumagin specimens is very minute. The expansion of the aperture tends to narrow the umbilicus, as it were at the last moment.

**Valvata virens** Tryon.

*Range.*—Clear Lake, California, to Vancouver Island, at Nanaimo.

A well marked species of more than usually trochoïd form, recalling *V. piscinalis* of Europe, but large, more solid, and when in good condition of a peculiarly elegant green tint. The figures given in Tryon's description are of immature specimens. Binney figures an adult specimen but does not give the measurements.

**Family VIVIPARIDÆ.**

**Genus Campeloma** Rafinesque.

![Fig. 95. Valvata virens Tryon, operculum, magnified.](image)

**Fig. 96. Campeloma decisum; b, operculum.**
Campeloma decisum Say.

Limnea decis Say, Nicholson's British Encyclopedia, 1st Am. ed., pl. III, fig. 6, 1817.
Melintho decis Binney, Land and Fw. Sh. N. Am., iii, p. 41, figs. 79–82, 1865.

Range. — Eastern North America from the Rio Grande to Nova Scotia, west to Nebraska, north to the Saskatchewan. Lake Superior to the Saskatchewan (Richardson); Lake of the Woods, Manitoba, (rare, Hanham).

It is not unlikely that the extension of the range of this species as far north as the Saskatchewan is unwarranted, so many of the data in Sowerby's list, in Richardson, seem erroneous, but the presence of the species in the Lake of the Woods seems authentic.

NAIADÉS.

In discussing the Naiades, the arrangement proposed by Mr. Chas. T. Simpson, in his recent Synopsis of the Naiades,¹ is adopted, which see for fuller synonymy.

Genus Lampsilis Rafinesque.

Lampsilis ventricosus Barnes.

Lampsilis ventricosus Simpson, Synopsis, p. 526, 1900.

Range. — Entire Mississippi drainage, the St. Lawrence system, southern drainage into Hudson Bay.

Lake Winnipeg; Battle River, Manitoba, and north to Nelson River! and its tributaries, in north latitude 57°.

Lampsilis luteolus Lamarck.

Unio luteola Lamarck, Anim. s. Vert., vi, p. 79, 1819.—Sowerby, Conch. Icon., xvi, Mon. Unio, pl. LVIII, figs. 293, a–b, 1867.
Lampsilis luteolus Simpson, Synopsis, p. 534, 1900.

Range. — Entire Mississippi drainage and southwest to the Brazos River, Texas; entire Dominion of Canada east of the Rocky Mountains and north to the Red River of the North!

Lampsilis borealis Gray.

*Unio borealis* GRAY, Ottawa Naturalist, 1882, p. 53, plate with three figures.
*Lampsilis borealis* (GRAY) SIMPSON, Synopsis, p. 535, 1900.

*Range.*—St. Lawrence drainage. Lake of the Woods! Ottawa, Ontario!

Lampsilis radiatus Gmelin.

*Conrad, Mon.*, ii, p. 24, pl. x, fig. 2, 1836.
*Lampsilis radiatus* SIMPSON, Synopsis, p. 535, 1900.

*Range.*—St. Lawrence and Atlantic drainage, south to North Carolina. Manitoba.

Lake Winnipeg! Saskatchewan River! Nelson River drainage! Great Slave Lake (Kennicott)!

Lampsilis ligamentinus Lamarck.

*Unio ligamentina* LAMARCK, Anim. s. Vert., vi, p. 72, 1819. —

*KÜSTER, Conch. Cab., Mon. Unio*, p. 23, pl. iii, fig. 3, 1852.
*Lampsilis ligamentinus* SIMPSON, Synopsis, p. 539, 1900.

*Range.*—Mississippi drainage, irregularly distributed in the St. Lawrence drainage.

Roseau River and Millwood, Assiniboine River, Manitoba.

Lampsilis rectus Lamarck.

*Unio recta* LAMARCK, Anim. s. Vert., vi, p. 74, 1819.—

*KÜSTER, Conch. Cab., Mon. Unio*, p. 35, pl. vi, fig. 1, 1852.
*Lampsilis rectus* SIMPSON, Synopsis, p. 544, 1900.

*Range.*—Entire drainage of the Mississippi and Alabama Rivers; St. Lawrence system, Red River of the North, Roseau and Assiniboine Rivers in Manitoba!

Lampsilis ellipsiformis Conrad.

*Unio ellipsiformis* CONRAD, Mon., viii, p. 60, pl. xxxiv, fig. 1, 1836.

*Unio spatulatus* LEA (1845), Trans. Am. Phil. Soc., x, p. 80, pl. viii, fig. 22, 1848.
*Lampsilis ellipsiformis* SIMPSON, Synopsis, p. 557, 1900.

*Range.*—Mississippi drainage north of Lat. 38°, St. Lawrence drainage, in part; Manitoba.

Red River of the North! Lake Winnipeg, Manitoba.

Lampsilis alatus Say.

*Unio alatus* SAY, Nicholson’s Encycl., 1st Am. ed., Art. Conchology, ii, pl. iv, fig. 2, 1817.—

*Conrad, Mon.*, vii, p. 57, pl. xxxi, 1836.
Lampsilis (Proptera) alatus Simpson, Synopsis, p. 567, 1900.

Range. — Entire drainage of the St. Lawrence; of the Mississippi north of Arkansas; Alabama; Manitoba. Red River of the North!

Lampsilis gracilis Barnes.

Lampsilis gracilis Simpson, Synopsis, p. 573, 1900.

Range. — Eastern Texas; Mississippi, and St. Lawrence drainage; Manitoba. Red River of the North!

Genus Strophitus Rafinesque.

Strophitus rugosus Swainson.

Anodonta rugosa Swainson, Zool. Ill., 1st ser., ii, pl. xcvi, 1822.

Anodonta edentula Férussac, Mag. de Zool., Guerin, 1835, p. 25.

Anodon areolatus Swainson, Zool. 111., 2d ser., i, pl. xviii, 1829.

Anodonta tetragina Lea (1845), op. cit., x, p. 82, pl. viii, fig. 25, 1845.

Anodonta arkansasensis Lea, op. cit., xi, p. 293, pl. xxix, fig. 56, 1852.

Anodonta shafteriana Lea, op. cit., x, p. 288, pl. xxvi, fig. 50, 1852.

Alasmodona rhombica Anthony, Am. Journ. Conch., i, p. 158, pl. 12, fig. 5, 1865.

Anodonta salmonea Clessin, Conch. Cab., Mon. Anodonta, p. 91, pl. xxiv, figs. 1–2, 1873.

Anodonta pavonia Lea.

Range. — St. Lawrence system; the whole of the Mississippi drainage, Texas, Alabama, the Atlantic drainage; Manitoba.

Red River of the North! Lake Winnipeg! Great Playgreen Lake! Saskatchewan River.

Genus Anodonta Lamarck.

Anodonta beringiana Middendorff.

Anodonta cellensis var. beringiana Midd., Sib Reise, ii, p. 284, pl. xxviii, figs. 4–7, pl. xxix, figs. 1–4, 1851.

Range. — Drainage into Bering Sea from Asia and America; also Cook Inlet drainage.

Kenai Peninsula! Kuskokwim River near Redoubt Kolmakof! Yukon River below Anvik, in pools and quiet sloughs left by the
receding freshets! Avacha Bay, Kamchatka! Amur River! eastern Siberia and Mongolia.

**Anodonta kennerleyi** Lea.

**Range.** — Puget Sound! British Columbia.

**Anodonta oregonensis** Lea.

**Range.** — Northern California, Oregon and British Columbia; eastward to Great Salt Lake, Utah.

Vancouver Island, B. C., abundant near Victoria, and at Nootka; Sumas Lake, Fraser River valley, B. C. Shushwap Lake; Nicola Lake and Okanogan Lake, B. C.; Kadiak Island, Alaska (Fisher).

**Anodonta nuttalliana** Lea.

*Anodon triangularis* Sowerby, Conch. Icon., xvii, pl. xxix, fig. 56 b, 1870.

**Range.** — California in the Sacramento River, and northward to British Columbia, Nootka and Clayoquot Sound, Vancouver Island; Chilliwak Lake, Nicola Lake and Shushwap Lake, British Columbia.

**Anodonta wahlamatensis** Lea.

*Anodonta wahlamatensis* Lea, Trans. Am. Phil. Soc., vi, p. 78, pl. xx, fig. 64, 1838.

*Anodon rostratus* Sowerby, Conch. Icon., xvii, pl. ii, fig. 4, 1872.

*Anodonta rotundata* Simpson, Synopsis, p. 629, in synonymy, 1900, not of Trask.

**Range.** — Utah and westward, California to British Columbia in the Pacific.

Nootka, Vancouver Island; Sumas Lake and Prairie, Fraser River valley, British Columbia.

**Anodonta marginata** Say.

Anodonta subcarinata Currier, Am. Journ. Conch., iii, p. 113, pl. vi, fig. 5, 1867.
Anodonta exilis Sowerby, Conch. Icon., xvii, pl. xxii, fig. 84, 1869.

Range. — Drainage of the St. Lawrence River basin, including the lakes.

Range. — Atlantic drainage from Virginia northward, St. Lawrence drainage, Saskatchewan basin.

Manitoba in Lake Winnipeg! and Souris River; lower Saskatchewan River!

Anodonta implicata Say.

Range. — Entire Mississippi system and southwest to Texas; upper St. Lawrence drainage; Manitoba.

Red River of the North! Shoal Lake; Souris River! Fairford River! and Lake Winnipeg, Manitoba!

Variety gigantea Lea: Manitoba.

This variable and widely extended species is responsible for many synonyms cited by Mr. Simpson. It appears that the Manitoba and
perhaps the upper St. Lawrence localities may owe its presence to capture of part of the Mississippi drainage, owing to changes of level, elsewhere referred to.

**Anodonta kennicotti** Lea.

*Anodonta simpsoniana* Lea, *op. cit.*, p. 56, 1861; p. 212, pl. XXXII, fig. 281, 1862.

**Range.** — Upper and middle St. Lawrence system. Mackenzie drainage to Great Slave Lake.

Lake of the Woods; Manitoba Lake; Lake Winnipeg! Grand Rapids of the Saskatchewan! Ekwan River, Keewatin; Fort Simpson, Mackenzie River! Fort Erie and Fort Rae! Great Slave Lake; Buffalo Lake, Methy Portage, Saskatchewan.

This is the most characteristic Naiad of the central Boreal region and reaches perhaps farther north (Lat. 63°) than any other species in American waters.

**Anodonta pepiniana** Lea.

**Range.** — Upper and middle St. Lawrence drainage, Saskatchewan basin.

Lake Winnipeg! Manitoba. Attawapiskat River, eastern Keewatin.

**Genus Gonidea** Conrad.

**Gonidea angulata** Lea.

*Anodon biangulata* Sowerby, Conch. Icon., xvII, pl. XXIII, figs. 8, a–b, 1869.

**Range.** — Central California, north to British Columbia and eastward to Idaho.

Columbia River near Fort Colville!

This singular shell hardly more than crosses the boundary, so far as reported. According to Stearns and Hemphill this species buries itself obliquely in the rather hard bed of rapid streams, so that the flattened posterior portion lies horizontally even with the bottom, and offers no resistance to the current. Whether the flattening and consequent angulation of the valves is a modification due to the burrowing habit and the influence of its environment, or not, cannot yet be positively stated.
Genus **Anodontoides** Simpson.

*Anodontoides ferussacianus* Lea.
*Anodontoides buchanensis* Lea, *op. cit.*, p. 47, pl. xiv, fig. 43, 1838.
*Anodontoides argentea* Lea, *op. cit.*, viii, p. 223, pl. xix, fig. 41, 1842.
*Anodontoides ferruginea* Lea, *op. cit.*, viii, p. 225, pl. xix, fig. 43, 1842.

*Anodontoides oblita* Lea, *op. cit.*, p. 46, pl. xxviii, fig. 52, 1852.
*Anodontoides subcylindracea* Lea, *op. cit.*, vi, p. 106, pl. xxiv, fig. 117, 1838.

Range. — Mississippi drainage, St. Lawrence, Red River of the North, and Saskatchewan basins.
Lake Winnipeg! Lake of the Woods!

Genus **Symphynota** Lea.

Subgenus **Lasmigona** Rafinesque.

*Symphynota costata* Rafinesque.

*Alasmidonta rugosa* Barnes, Am. Journ. Sci., vi, p. 278, pl. xiii, fig. 21, 1823.

Range. — Mississippi and St. Lawrence basins.
Manitoba in Roseau River!

Subgenus **Pterosygna** Rafinesque.

*Symphynota complanata* Barnes.

*Alasmidonta complanata* Barnes, Am. Journ. Sci., vi, p. 278, pl. xiii, fig. 22, 1823. — Baker, Moll. Chicago Area, i, p. 60, pl. viii, figs. i–2, pl. ix, figs. 1–4, 1898.
*Complanaria gigas* Sowerby, Conch. Manual, fig. 141, 1839; 2d ed., p. 115, fig. 141, 1842.

Range. — Missippian drainage north of Arkansas on the west and Tennessee on the east; Upper St. Lawrence and its tributaries. The variety *katherinae* northward from Lake Superior to the Mackenzie and Keewatin.

Lake Winnipeg! Shell River and Lower Saskatchewan! Nelson River drainage; Assiniboine River; Red River of the North! Battle River, Manitoba.
Genus **Margaritana** Schumacher.

**Margaritana margaritifera** Linné.

Typical form:

- *Alasmodonta arcuata* Barnes, Am. Journ. Sci., vi, p. 277, pl. xii, fig. 20, 1823.
- *Unio sinuata* C. Pfeiffer, 1825 ; + *U. roissyi* Michaud, 1831 ; + *U. tristis* Morelet, 1845 ; + *U. crassissimus* (Klein) Lea, 1836.
- *Unio (Alasmodonta) dahuricus* Middendorff (1850), Sib. Reise, ii, p. 275, pl. xxvi, figs. 3–5, 1851.
- *Unio complanatus* Middendorff, Sib. Reise, ii, p. 273, pl. xxvii, figs. 1–6, 1851.

Range of the type. — The whole of northern Europe and western Siberia. In northeastern Asia from the Upper Amur basin and southern Mongolia, Kamchatka, and Sakhalin Island. In America on Anticosti Island; Quebec Province, eastern Canada; New England and New York. Also, isolated from the eastern area by a wide gap, in the Lower Saskatchewan near Lake Winnipeg.

Range of the variety. — California, in the Sierra, Plumas Co., at 7,400 feet above the sea! Sacramento River; Yuba River; Oregon; Washington at Wallawalla; northwestern Montana in the headwaters of the Missouri! (only) above Fort Benton, but not reported lower down; Victoria and Nanaimo! Vancouver Island; Fraser River; Kakwous Lake (4,000 feet elevation) and streams in Lat. 50°, British Columbia; Naha Bay, Alaska, abundant near sea level in small lake, Lat. 55°35 North!

The most obvious distinction between the typical form and variety *falcata* lies in the purple nacre of the latter, which is often extremely rich and beautiful, though in old cabinet specimens usually much faded. The specimens above the falls in the headwaters of the Missouri may have been captured with streams by orographic changes, or transported in the glochidium stage attached to fishes; at any rate
they are of the Pacific type, and are not found below the site of Fort Benton, so far as yet reported. It is quite evident that much scientific interest attaches to a thorough knowledge of the distribution of this species, with its possible relation to geologic changes and the results of glaciation. It is to be hoped that any data bearing on this matter will be carefully preserved and put on record by travelers and others in these regions.

Genus **Unio** Retzius.

**Unio complanatus** Solander.

**Unio complanatus** SIMPSON, Synopsis, pp. 720-5, 1900.

**Range.** — Atlantic drainage from Georgia to the St. Lawrence system. Also in the Saskatchewan River.

North shore of Lake Superior; Lake Nipissing, etc.

Genus **Quadrula** Rafinesque.

**Quadrula plicata** Say.

**Quadrula plicata** SIMPSON, Synopsis, p. 767, 1900.

**Range.** — Mississippi drainage from Arkansas and Tennessee northward; Western Michigan, Red River of the North, Lake Winnipeg and the Saskatchewan.

The variety *hippocae* occurs in Lakes Erie, Michigan, and Winnipeg.

**Quadrula undulata** Barnes.

*Unio undulata* BARNES, Am. Journ. Sci., vi, p. 120, pl. ii, 1823.

*Unio costatus* SAY, Am. Conch., vi, No. 41, 1834; not of Rafinesque.

**Quadrula undulata** SIMPSON, Synopsis, p. 769, 1900.

**Range.** — Mississippi and St. Lawrence drainage generally, Texas and Alabama; Red River of the North; Lake Winnipeg; the Saskatchewan River.

**Quadrula heros** Say.

*Unio heros* SAY, New Harmony Diss., II, No. 19, p. 291, 1829.—CONRAD, Mon., xii, p. 107, pl. lix, 1840.

**Range.** — Nuevo Leon, Mexico; Tombigbee River, Alabama. The Mississippi system generally; Red River of the North, Manitoba.
Quadrula lachrymosa Lea.

Unio asperrimus Lea, op. cit., iv, p. 71, pl. v, fig. 3, 1831.
Unio quadratus Say, Am. Conch., vi, pl. LIII, 1834; not of Rafinesque.
Quadrula lachrymosa Simpson, Synopsis, p. 776, 1900.

Range.—Entire Mississippi drainage; various localities in the St. Lawrence system; Red River of the North, Manitoba, abundant.

Quadrula rubiginosa Lea.

Unio flavus Conrad, 1834.—Say, Am. Conch., vi, 1834.—Conrad, Mon., ix, p. 74, pl. xii, fig. 2, 1837.
Unio trigonus Sowerby, Conch. Icon., Mon. Unio, XVI, pl. LXIV, fig. 322, 1868.
Quadrula rubiginosa Simpson, Synopsis, p. 786, 1900.

Range.—Entire Mississippi drainage; eastern Texas; St. Lawrence drainage; Red River of the North! Manitoba; Nelson River! Keewatin; Red and Roseau Rivers and Lake Winnipeg, Manitoba.

Family SPHÆRIIDÆ.

This family is reviewed in Trans. Wagner Institute, vol. iii, part vi, pp. 1439–60, and a summary of the arrangement adopted is also given in Proceedings Biological Society of Washington, xvi, pp. 5–8, 1903. This arrangement in effect is that which is adopted on the present occasion. The specific synonymy is mainly due to the late Temple Prime, who kindly named the Alaskan specimens collected previous to his death. Some later arrivals have been examined by Dr. Sterki. I have seen no specimens or figures of the species from Port Clarence named by Westerlund, and they are introduced on his authority. It is probable that a considerable reduction will eventually be had in the number of nominal species, especially of Corneocyclus.

Genus Sphaerium Scopoli.

Subgenus Sphaerium s. s.

Sphaerium simile Say.

Cyclus similitus Say, Nicholson’s Encycl., 1st Am. ed., pl. 1, fig. 9, 1817.
Sphaerium sulcatum Prime, Mon. Am. Corbic., p. 33, fig. 25, 1865.

Range.—United States, east of the Mississippi River; Canada; Manitoba.

Lake Superior; Red River of the North; Lake Winnipeg; Pine
FAMILY Sphaeriidae

Creek and Fort Pelly, Manitoba; Lower Saskatchewan River at Grand Rapids!

**Fig. 97. Sphaerium simile** Say.

This species is the *Cyclas saratogea* of Lamarck and has numerous other synonyms. It is the largest species of the group in North America, but, judging by the records, rather irregularly distributed. The Lamarckian locality is Lake George; Say's specimens are from the vicinity of Philadelphia.

**Sphaerium striatinum** Lamarck.

*Sphaerium striatinum* PRIME, Mon. Am. Corbic, p. 37, fig. 29, 1865.

*Range.*—North America generally, east of the Sierra Nevada Mountains, from Alabama to the Upper Mackenzie.

Hell Gate River (Columbia drainage), Montana; Humboldt River, Nevada (Hepburn); in Manitoba at Lake Winnipeg; Great Playgreen Lake; York Factory, Keewatin; Pasqua Lake, Assiniboia! Saskatchewan River at Grand Rapids! Mackenzie River at old Fort Simpson!

So far as the records indicate, the place of this species is east of the Rockies, but in at least two places it has been transferred to the head-waters of streams flowing westward. In the East it is perhaps the most common of the *Sphæria*, taking much such a place as *S. corneum* does in the European fauna.

* Sphaerium aureum* Prime.

*Sphaerium aureum* PRIME, Mon. Am. Corbic, p. 35, fig. 26, 1865.

*Range.*—Lake Superior.

It is probable that this species crosses the line into Canada, though not yet searched for in that region.

**Sphaerium walkeri** Sterki.

*Sphaerium walkeri* STERKI, Nautilus, xiv, p. 142, April, 1901.
Range.—Frances Lake and Finlayson Lake, Yukon District, Liard River drainage (Dawson); Lake Michigan, 12 fathoms (Walker).

Identified by Dr. Sterki, a species related to *rhomboideum* and *occidentale*, but yet unfigured.

**Sphaerium solidulum** Prime.

*Sphaerium solidulum* Prime, Mon. Am. Corbic., p. 36, fig. 27, 1865.

**Range.**—Eastern United States, from New Mexico and Louisiana to the Great Lakes, and Manitoba.

In Manitoba, at Winnipeg, Brandon, and the Red River of the North; in Alberta, at Egg Lake.

**Sphaerium stamineum** Conrad.

*Sphaerium stamineum* Price, Mon. Am. Corbic., p. 38, fig. 30, 1865.

**Range.**—Eastern United States, northward to Manitoba.

Manitoba (Hanham).

The type locality for this species is Alabama. In 1865 Mr. Prime united with it the *Cyclas fuscata* of Rafinesque (Ohio) and the *C. bulbosa* Anthony from Arkansas. Later collectors have found it widely distributed over the eastern portion of the continent.

**Sphaerium rhomboideum** Say.

*Cyclas elegans* Adams, Boston Journ. Nat. Hist., iii, p. 330, pl. iii, fig. 11, 1840.

*Sphaerium rhomboideum* Prime, Mon. Am. Corbic., p. 39, fig. 31, 1865.

**Range.**—New England to Michigan, and northwestward.

Lake Superior; Manitoba at Pine Creek and in Lake Winnipeg.
FAMILY SPHÆRIIDÆ

Left bank of the Yukon River, Alaska, 30 miles below the mouth of the Tanana! In duck's crop at Pender Island, British Columbia. This attractive species is apparently sporadic or local in its habitats, but if intelligently sought for would probably be found more often. It is not yet positively known from British Columbia, but there is little reason to doubt it will be found there when the fauna is better known. So far it seems to be rather rare everywhere.

*Sphærium dentatum* Haldeman. Figure 102.

*Sphærium dentatum* PRIME, Mon. Am. Corbic., p. 40, fig. 32, 1865.

*Sphærium fabale* Prime. Figure 103.

*Sphærium fabalis* PRIME, Mon. Am. Corbic., p. 40, fig. 33, 1865.

*Range.* — Eastern United States and northward, Battle River, Alberta.

This species was originally described from specimens collected in Lake Superior by Louis Agassiz, but has since been recognized from Georgia, Virginia and Tennessee. It is remarkable for its compressed form and inconspicuous beaks.

*Sphærium occidentale* Prime.

*Range.* — Northern United States, Vermont to Washington and northward.

Hell Gate River (Columbia drainage), Montana! Lower Saskatchewan River, near Lake Winnipeg; Spokane Falls, Wash.

*Sphærium nobile* Gould.

*Sphærium nobile* PRIME, Mon. Am. Corbic., p. 41, fig. 35, 1865.

Blackfoot River, Idaho! Seattle, Wash.

This is not figured by Gould in Expedition Shells, as stated by Prime. It closely resembles _S. dentatum_ Hald., but is less inflated, while the young are smooth.
Sphaerium patella Gould.

Sphaerium patella Prime, Mon. Am. Corbic., p. 42, fig. 36, 1865.

Range. — Northern California to British Columbia.
Healdsburg, Calif.; Wallawalla, Vancouver and Seattle, Wash.; Nanaimo, and in duck's crop at Pender Island, British Columbia.

Sphaerium emarginatum Prime.

Sphaerium emarginatum Prime, Mon. Am. Corbic., p. 43, fig. 38, 1865.

Range. — Lake Superior; Saskatchewan River at Grand Rapids, near Lake Winnipeg.

Sphaerium flavum Prime.

Sphaerium flavum Prime, Mon. Am. Corbic., p. 43, fig. 39, 1865.

Sphaerium tumidum Baird.

Range. — Sumas Prairie, Fraser River valley, British Columbia. This species appears not to have been figured or subsequently recognized by collectors.

Sphaerium spokani Baird.

Range. — Spokane and Kootenai Rivers, eastern British Columbia. Unfigured, and not recognized by later collectors.

Sphaerium (Musculium) raymondi Cooper.

Sphaerium raymondi J. G. Cooper, Proc. Acad. Sci. Calif., 2d series, iii, p. 74, pl. 1, figs. 1–8, 1890.
Primella raymondi Cooper, *op. cit.*, p. 82.

*Range.* — Alpine region of the Sierra Nevada, Calif., to 8,700 feet; Seattle, Spokane Falls, and Chehalis River, Wash.; Idaho; Vancouver Island, British Columbia (Roper).

*Sphærium (Musculium) partumeium* Say.
*Sphærium partumeium* Prime, Mon. Am. Corbic., p. 45, fig. 42, 1865.

*Range.* — United States from Nebraska eastward, south to the Gulf of Mexico and north to Manitoba.

*Sphærium (Musculium) jayanum* Prime.
*Sphærium jayanum* Prime, Mon. Am. Corbic., p. 46, fig. 43, 1865.

*Range.* — Northern United States from Iowa eastward, Canada, and northward.

Fig. 108. *Sphærium jayanum* Prime.

Lake Superior; Fort Ellice, Manitoba; in Alberta at McLeod, Olds, Crow Lodge Creek, and Little Bow River.

*Sphærium (Musculium) tenue* Prime. Figure 109.
*Sphærium tenue* Prime, Mon. Am. Corbic., p. 47, fig. 44, 1865.

*Range.* — Maine, Canada, British America and northern Alaska. Souris River, Manitoba; Saskatchewan River at Grand Rapids; Upper Mackenzie River at old Fort Simpson! left bank of the Yukon, thirty miles below the Tanana River mouth, Alaska!

*Sphærium (Musculium) transversum* Say. Figure 110.
*Sphærium transversum* Prime, Mon. Am. Corbic., p. 48, fig. 45, 1865.

*Range.* — United States east of the Rocky Mountains and northward to Canada and Manitoba.
Stomach of sturgeon, Great Playgreen Lake, Keewatin, N. Lat. 54°.

**Fig. 109.** *Sphærium tenue.*
**Fig. 110.** *Sphærium transversum* Say, with foot and siphons extended.
**Fig. 111.** *Sphærium lenticula.*

*Sphærium (Musculium) truncatum* Linsley.

*Sphærium truncatum* PRIME, Mon. Am. Corbic., p. 51, fig. 50, 1865.

**Range.** — Eastern United States from Colorado to Maine, south to the Ohio River and northward to Athabaska.

Methy Lake, Athabaska (Richardson).

This species is quite similar to the European *Cyclas calyculata*, type of the subgenus, and was mistaken for it by C. B. Adams in 1841.

*Sphærium (Musculium) lenticula* Gould.

*Sphærium lenticula* (GOULD) PRIME, Mon. Am. Corbic., p. 51, fig. 51, (syn. exclus.), 1865.

**Range.** — Carson and Klamath Rivers, California; Nanaimo, Vancouver Island, British Columbia.

This species, named in MS. by Dr. Gould and described by Prime, is not the same as the *Lucina lenticula* Gould, described from Patagonia in the Mollusca of the Exploring Expedition. The latter, by an engraver's error, was called on the plate (but not in the text) *Cyclas lenticula*, and this seems to have misled Mr. Prime, who may not have had access to the text of this rare volume.

* *Sphærium stagnicola* J. de C. Sowerby.

*Cyclas stagnicola* SOWERBY, in Richardson, Fauna Bor. Am., iii, p. 316, 1836, Methy Lake, Athabaska.

* *Sphærium medium* J. de C. Sowerby.

*Cyclas media* SOWERBY, op. cit., Methy Lake, Athabaska.

The two names above cited from Sowerby are not described in Richardson's work and I am unable to find any other reference to them in the literature. I presume they are undescribed.
*Sphaerium primeanum* Clessin.

*Sphaerium primeanum* Clessin, Malak. Blät., xxv, p. 122, pl. v, figs. 1, a–b, 1878.

**Range.** — Portland, Oregon; Seattle, Wash.

This species, which has a remarkable resemblance to a *Bornia*, judging by the figure, is not otherwise known to me, but, if the localities given are correct, may also extend to British Columbia. According to Roper it closely resembles *S. rhomboideum* Say.

**Genus Corneocycas** Fréussac.

(+ *Pisidium* C. Pfeiffer.)

**Corneocycas (Phymesoda) virginica** Gmelin.

*Tellina virginica* Gmelin, Syst. Nat., vi, p. 3236, 1792; based on Lister, Conch., pl. CLIX, fig. 15, from Virginia.

*Cyclus dubia* Say, Nicholson’s Encycl., 1st Am. ed., pl. i, fig. 10, 1817.

**Range.** — United States, east of the Rocky Mountains, northward to British America and Alaska.

Lake of the Woods; Manitoba; Yukon River, Alaska, thirty miles below the Tanana River mouth! also at Nulato! and the Mission! Lake Superior, near St. Ignace Id., in 8 to 13 fathoms (S. I. Smith).

**Corneocycas (Phymesoda?) idahoensis** Roper.

**Range.** — Old Mission, northern Idaho (Hemphill); Seattle, Wash. Stewart River, Yukon District, Dawson (*fide* Sterki).

**Corneocycas (Phymesoda) scutellata** Sterki.

*Pisidium scutellatum* Sterki, Nautilus, x, p. 66, Oct., 1890.

**Range.** — Lake Michigan to Montana; Lake Patten, Wash., Pine Lake, Mich.; Orchard Lake, Minn.; Sheldon, Montana; Frances Lake, Liard River, Yukon District (*fide* Sterki), collected by Dawson in 1887.

**Corneocycas æquilateralis** Prime.

**Range.** — Maine to Michigan, northward and westward to Alaska.
Kotzebue Sound, Alaska! in marl associated with mammoth bones, at Elephant Point. Bering Island, Bering Sea!

The specimens above referred to were identified for me by Mr. Prime.

**Corneocyclas (Cymatocyclas) compressa** Prime.

**Range.** — Maine to California; Canada, the Yukon.

Lake Superior, near Ignace Id., in 4-6 fathoms; White Pine, Nevada; Sierra Nevada to 9,000 feet near Summit, Calif.; Ventura Co., Calif.; Vancouver Island, British Columbia (Raymond); Green Lake, Seattle, Wash.; Stewart River, Yukon District (*fide* Sterki).

**Corneocyclas variabilis** Prime.

**Range.** — Eastern United States, north of Virginia; Colorado, and northward; Seattle, Wash.

Pine Creek, Manitoba; Stewart River, Yukon District (*fide* Sterki).

**Corneocyclas abdita** Haldeman.

**Range.** — North America, from Honduras northward to Alaska.

Marl Lake, Anticosti! Lake Superior in 4 to 13 fathoms near Ignace Island; Manitoba; Assiniboia at Qu'Appelle! Alberta, at Laggan, Red Deer, Olds, McLeod, Battle River, up to 5,200 feet elevation; east slope of the Sierra Nevada up to 7,100 feet; in Colorado up to 9,300 feet; west slope of the Sierra below 5,300 feet in California; Seattle, Wash.; in Alaska at Seldovia, Cook Inlet! Coal Harbor! Unga Island, Shumagins, in small pools on the tundra; Akun Island! Aleutians; the Yukon River, 30 miles below the mouth of the Tanana! and Bering Island, Bering Sea!

This is the most common and widespread species, out of the varieties of which many nominal species have been made.
*Corneocyclas abyssorum* Stimpson.

*Pisidium abyssorum* (Simp.) Hoy, Trans. Wisconsin Acad. Sci., I, p. 100, 1872 (err. typ.).  

Lake Michigan; Lake Superior to a depth of 159 fathoms (food of *Coregonus*); Pine Lake, Mich.; Green Lake, Wisconsin.  
This is another of the extra-limital species which search will probably reveal in Lake Winnipeg and other northern lakes.

**Corneocyclas ventricosa** Prime.

**Range.** — Massachusetts, Canada, and northward to Great Slave Lake.

**Corneocyclas rotundata** Prime.

**Range.** — Lake Superior region; Manitoba; St. Paul Island, Bering Sea!

**Corneocyclas steenbuchii** Möller.

*Cyclus steenbuchii* Möller, Index Moll. Grönl., p. 20, 1842.  

**Range.** — Greenland, on the west coast! Iceland! Ungava, Labrador.  
This species appears to be unfigured, but there are specimens in the Jeffreys collection from Iceland as well as Greenland. It appears to belong to the section *Cyclocalyx*.

**Corneocyclas occidentalis** Newcomb.

Prime, Mon. Am. Corbic., p. 73, 1865.

**Range.** — California to British Columbia.  
East slope of Sierra Nevada, in California, to 9,700 feet. Nanaimo, Vancouver Island, British Columbia; Spokane Falls, Wash.
This unfigured species has been regarded by Roper as only a mutation of C. abdita Haldeman.

**Corneocyclas ultramontana** Prime.

*Pisidium ultramontanum* Prime, Mon. Am. Corbic., p. 75, fig. 85, 1865.

*Range.*—Canoe Creek, California; Seattle, Wash.; Nanaimo, Vancouver Island, and Pender Island! British Columbia.

**Corneocyclas arctica** Westerlund.

*Range.*—Port Clarence, Alaska.

**Corneocyclas nivalis** Westerlund.

*Pisidium nivale* WESTERLUND, op. cit., p. 218, 1885.

*Range.*—Port Clarence, Alaska.

**Corneocyclas glacialis** Westerlund.

*Pisidium glaciale* WESTERLUND, op. cit., p. 218, 1885.

*Range.*—Port Clarence, Alaska.

*Corneocyclas sibirica* Clessin.

*Range.*—Western Siberia, on the Yenisei River to 60° 50' N. Lat., ? Port Clarence, Alaska.

*Corneocyclas borealis* Clessin.

*Range.*—Western Siberia at Lusino. ? Port Clarence, Alaska.

The preceding five species are ascribed to Port Clarence on the authority of the literature solely. I have not seen specimens of any of them. I suspect that the *C. sibirica* and *borealis* reappear in the form of new species, among the three nominal species preceding them.

**Corneocyclas pulchella** Jenyns.

*Range.*—Middle and Northern Europe to 69° N. Lat. Arctic America?

Methy Lake, Athabaska (Richardson).
*Corneocyclas randolphi* Roper.

*Pisidium randolphi* ROPER, Nautilus, IX, p. 99, Dec., 1895.

**Range.**—Seattle, Washington.

This species is finely striated, very much like *C. abdita* in general form, but of a peculiar and unique greenish-yellow color. It may very likely extend into British Columbia.

**Corneocyclas** (*Tropidocyclas*) *henslowana* Sheppard.

*Cyclas appendiculata* (LEACH MS.) TURTON, Man., ed. 1, p. 15, pl. XV, fig. 6, 1831.—SOWERBY, in Richardson, Fauna Bor. Am., III, p. 316, 1836.

*Pisidium henslowianum* JENYNS, Mon. *Cyclas*, p. 20, pl. XXI, figs. 6, 7, 1832.

**Range.**—Europe north of the Alps; Canada; British America; Hamilton Bay, Lake Ontario; Lake Superior to Lake Winnipeg (Richardson).

The record from Richardson was naturally thought to be a misidentification, but the recent discovery in Lake Ontario of undoubted specimens of this species, leads to the belief that Sowerby, who certainly should have known a common British species, may after all have been correct.

In closing the list of *Sphæriidæ* I may be allowed to observe that so large a part of it is derived from the literature, and not from the present examination of specimens, that I do not feel the confidence in the validity of all the species, or the correctness of all the identifications that I might have felt under other circumstances. Until the very numerous species which have been named among American *Pisidia* of late years, shall have been adequately illustrated and some knowledge gained of the range of variation in these minute forms, a healthy skepticism in regard to our population of this genus will doubtless continue to prevail among collectors of fresh water shells.

Mousson, Albert.  

Note.—This paper was only discovered after the completion of the present memoir. Nearly all the species mentioned in it are from the upper waters of the Amur River, or from Vladivostok. Succinea insularis Mousson, from an island at the mouth of the Amur, is the only addition to the species properly belonging to the Primorski province, treated of in my discussion of the species of the Northeast coast of Siberia, but several are added to the list of Mongolian elements of the fauna of the Amur drainage.

HYDROIDS OF THE EXPEDITION
The following paper on the Hydroids of the Expedition, by Professor C. C. Nutting, of the University of Iowa, was originally published in the Proceedings of the Washington Academy of Sciences, vol. III, pp. 157–216, May 11, 1901. It is here reprinted from the same electrotype plates, so that it may be quoted exactly as if it were the original. The original pagination has been preserved and transferred to the inner or hinge side of the page, where it is enclosed in brackets, thus [159]; while the consecutive pagination of the present volume has been added in the usual place. In the plates the original number and running headline, slightly abbreviated, have been preserved [in brackets], while the volume designation and serial plate number have been added in the usual place. The original text references to the plates are unchanged. The present headpiece and title have been substituted for the running heading of the Academy's Proceedings and the original title, which was: Papers from the Harriman Alaska Expedition. XXI. The Hydroids. No other alterations have been made.

EDITOR.
HYDROIDS OF THE EXPEDITION

BY C. C. NUTTING

CONTENTS

Introduction ........................................... 175
Geographic distribution ............................... 176
Systematic discussion .................................. 181

INTRODUCTION.

The collection of Hydroida secured by the Harriman Expedition is of exceptional interest, and proves to be one of the most important and most extensive collections of these beautiful forms of marine life thus far made in Alaskan waters. Our previous knowledge of the Hydroid fauna of this region rested almost exclusively on the collection made by Dr. W. H. Dall and his associates during the years 1871–1874 and reported on by Dr. S. F. Clark. 1 The number of species listed in Clark's report is 41, in which was included Coppinia arcta, now known to be merely the gonosome of Lafaea. Of these 40 species, 15 are well known British forms, and only one was then known from the Atlantic coast of the United States. The remaining 24 species were new.

[157] (175)
In 1878 C. Mereschkowsky added a single species to the Alaskan fauna, bringing the total up to 41.

No other additions were made until 1899, when I added eight, of which three were well known British species and five were new. That made a total of 49 species reported prior to the Harriman Expedition.

The collection here treated of comprises 53 species, 24 of which had been previously reported. Of the remainder, 9 were previously recorded from other localities, and 20 are new. Thus the Harriman Expedition has added about 60 percent to the number of species hitherto known from Alaskan waters. More than half of the species secured are new to Alaska and nearly 40 percent are new to science.

The whole number of species of hydroids now known from Alaska is 78. Considering the small amount of collecting that has been done in that region, compared with the extensive explorations of the coasts of Europe and the Atlantic coast of the United States, one may confidently expect that the waters of the far Northwest will prove to be very rich in hydroid life.

**GEOGRAPHIC DISTRIBUTION.**

A table is here given to indicate, first, the localities at which each species was collected by the Harriman Expedition, and second, the extent to which Hydroids have been distributed southward along meridional lines from what appears to have been a polar center of distribution. No attempt has been made to represent the complete distribution of the species.

A glance at the part of the table showing the distribution as represented in the collection secured by the expedition, shows an apparent poverty of the Hydroid fauna of the western, as compared with the eastern, portion of the territory explored. For convenience in such comparison the stations are arranged consecutively from east to west. The largest series were obtained at Berg Inlet in Glacier Bay; Yakutat Bay; and at Orca in Prince William Sound. These localities are all in deep bays, sheltered from storms and surrounded by rocky shores. On

1 Species marked by * are new.
account of the presence of perpetual ice in the form of glacier fronts and bergs, the water must be very cold the year around. Such a combination of conditions is particularly favorable to Hydroid life and accounts for the remarkably rich collections made at these places and also for the presence of so many arctic species. In this connection it is interesting to note the following paragraph written about twenty five years ago by Dr. Dall: "The material derived from the northwestern coasts of America, from Cook's Inlet south and east, indicates a series of Arctic colonies in favored localities, the future exploration of which offers a labor of the highest interest. These colonies are situated where the depth of water, the drippings of glaciers, and the high and adjacent shores of the Great Archipelago combine to reduce the temperature of the water below its apparently normal isotherm. Cook's Inlet affords one of them, one exists in the Gulf of Georgia, and others only await further exploration."¹ It should be noted, however, that nearly all of the Arctic species are well known forms belonging to the 'Holarctic Province' of authors, and that these species are of practically continuous distribution on all coasts in northern regions so far as explored.

In the same paper, Dr. Dall divides the coasts of America from Monterey, California, north and west, into three faunal areas, as follows: (a) the Oregonian, extending from Monterey to the Shumagin Islands; (b) the Aleutian, extending from the Shumagin Islands to the end of the Aleutian chain, and northward to the winter line of floating ice in Bering Sea; (c) the Arctic, limited on the shore line to the winter line of floating ice and passing southward indefinitely in deep water.

This paper deals chiefly with what Dr. Dall would call the Oregonian Fauna, only seven species having been secured to the westward of the Shumagin Islands. Of these seven species five are also found in his Oregonian Fauna, and the other two are new and known, thus far, from only one locality.

Dr. Clark, in reporting on the collection made by Dr. Dall, enumerates 25 species that occur west and north of the Shumagin Islands. Of these 25 species we now know that sixteen

also occur to the eastward of the Islands, while five have not been reported from any locality other than the ones where they were originally discovered. Our present knowledge therefore does not support the validity of Dr. Dall's division of faunae at the Shumagin Islands. It rather indicates a continuity of fauna from southern Alaska to the end of the Aleutian chain. Hydroid life appears to decrease as we go westward, but this may be only apparent and due to the more extensive exploration of the shores east of the Aleutian Islands.

Dr. Dall extends his Oregonian fauna down to Monterey, California. Reasoning again merely from the known distribution of hydroids, it would seem that Puget Sound is a natural region of demarcation between faunae, although the region from Puget Sound to San Francisco has been very little explored. In 1876 Dr. Clark published a paper on 'The Hydroids of the Pacific Coast of the United States south of Vancouver Island,' in which he gives a list of twenty-four species; of these only two, *Lafaxa dumosa* and *Sertularia argentea*, have as yet been reported north of Puget Sound. The same author, in reporting on Dr. Dall's collections from Alaska, notes as one of the main points of interest, the 'small number of species that are common to the Alaskan coast and the western shores of the United States from Vancouver Island southward.' In 1899 the present writer published a paper on 'Hydroida from Alaska and Puget Sound' in which it appears that out of twenty-two species from Puget Sound, only four have been reported farther south, while fifteen are now known to occur in Alaska. In the same year Mr. G. N. Calkins published a paper entitled 'Some Hydroids from Puget Sound,' in which some thirty species are noted, only two of which are known to occur south of Puget Sound.

From this study of the distribution of the Hydroids of the northwest coast of America, therefore, I am strongly persuaded that the region south of Puget Sound constitutes one distinct faunal area, and that the region from Puget Sound north and west to the end of the Aleutian chain constitutes another un-

---

broken faunal area that might properly be designated as *Alaskan*. From the number of arctic species included in this area it is not improbable that it extends northward along the shores of Bering Sea.

Dr. Clark agrees with Dr. Dall that there is a distinct faunal difference between the region east of the Shumagin Islands and that west of them. The material added since the publication of his paper, however, seems to prove that this difference is only apparent and due solely to lack of exploration.

The most important thing to be noted in that part of the table devoted to general distribution is the Holarctic distribution of a number of species. Of the eighteen species known to occur in the Arctic region, no less than fifteen also occur on the European coast, fourteen on the Atlantic coast of the United States, and thirteen on the Pacific coast as far south as Puget Sound. An examination of the table shows further, that the Hydroid fauna of Alaska, as represented by the Harriman collection, includes fifty-three species in all, of which eighteen are Arctic in fact, having been secured in Arctic waters; four others are in all probability Arctic, being found both in European and American waters; four are, so far as is known, confined to the Alaskan and Pacific coast south to Puget Sound; twenty-five are thus far known from Alaska only, and two are Californian. If we recognize the Alaskan faunal region as extending to Puget Sound, and include those species actually known to be Arctic, together with those in all probability Arctic, in a group which may justly be called Arctic, the following significant analysis of the faunal relations of the collection may be made: Alaskan species, twenty-nine; Arctic species, twenty-two; Californian species, two. This shows that fifty-five percent of the hydroid fauna as a whole is peculiar to Alaska, but that there has been a strong invasion from the Arctic regions of the Holarctic species constituting about forty-one percent of the collection, and that only two species, or less than four percent, are Californian. If all the species known to occur in Alaska were included in the computation the result would be a larger percentage of Alaskan species, a corresponding decrease of the Arctic species, and the addition of one or two Californian species.
THE HYDROIDS

SYSTEMATIC DISCUSSION.

The writer deems it unnecessary to attempt a complete synonymy of the well known European species contained in the Harriman collection and considers it sufficient to give, first, and in all cases, the original reference to the species; second, all obtainable references to the occurrence of the species on the Pacific Coast of America, and, third, a reference to verify the 'General Distribution' as given in the table just discussed. In this latter case only one reference will be given to verify the occurrence of a given species in each of the regions included in the right hand portion of the table.

As to the classification employed in this report, it seems best, on the whole, to pursue a conservative course, following pretty closely the lines laid down by the able British naturalists, Hincks and Allman. While it is true that the classification is in an unsatisfactory state, the writer does not feel that a thorough revision of the entire group of Hydroida should be attempted here, and frankly confesses his conviction that recent attempts in that direction have not been successful, though each contains valuable suggestions. Levinsen, for example, has made a notable contribution to our knowledge of the Campanulinidae in his able and careful exposition of the differences in the opercula of various species, but his genera founded solely on these structures appear to be artificial, as usually happens when a single character is made the basis of classification. In his terse characterization of the genera of Sertulariidae this author has been most fortunate, as well as in his masterly clearing up of the mystery concerning the gonosome of Lafaëa.

Schneider, also, has attempted to rearrange the Hydroida on a logical basis. Instead of multiplying groups, as has been the tendency of late, he has, in my opinion, gone far to the other extreme, uniting families that almost any other student acquainted with the group would regard as surely distinct. It seems unlikely that he will be followed in uniting such groups as the Tubulariidae and Pennaridæ in a single family, although one

1Medusær, Ctenopherer og Hydroider fra Grønlands Vestkyst, Copenhagen, 1893.

writer, Calkins, has followed his classification quite closely, and includes representatives of what would ordinarily be regarded as at least eleven families in five families as defined by Schneider.

It is not likely that classifications will ever represent anything but individual opinion, and it is probable that there will always be two sets of extremists who on the one hand will be too ready to multiply groups, and on the other will be too conservative to recognize real progress. The Hydroida offer unusual difficulties and consequently students of that group find agreement, even along the most general lines, practically impossible. The objective point of systematic discussion has been the attainment of a system of classification by which genera could be distinguished by means of the trophosome alone. This end, although in theory greatly to be desired, appears to be unattainable. The writer has chased this will-o-the-wisp for years, and is ready to abandon its pursuit as unprofitable. Abler men have had the same experience, and it appears to be pretty well established that in practice we must base generic distinctions on the gonosome alone, although the judgment of students will inevitably differ as to the extent to which this can be profitably done. Botanists have encountered the same difficulty in their study of the lower plants, such as the fungi, and have come to the same conclusion. In neither case has nature been working for the convenience of naturalists, and the fact should be accepted without a bootless chase after the unattainable.

**GYMNOLASTEA.**

Hydroida in which well differentiated hydrothecæ and gonangia are not present. What might be called ‘pseudo-hydrothecæ’ are found in some species as in *Eudendrium vaginatum* (see description of that species on pages 167–168).

Family **CORYNIDÆ.**

*Trophosome.*—Hydranth with a terete body and proboscis and scattered capitate tentacles only.

*Gonosome.*—Fixed sporosacs, or free medusæ with a very long manubrium, four marginal tentacles and four sense-bulbs with eye-spots.

CORYNE.

**Trophosome.**—Characters of the family.

**Gonosome.**—Reproductive elements produced in fixed sporosacs growing on the hydranth body.

CORYNE BRACHIATA sp. nov.

(Plate xiv, figs. 1, 2.)

**Trophosome.**—Colony forming a dense tuft of irregularly branching stems, sometimes attaining a height of about \( \frac{3}{4} \) inch. Stems and branches profusely and regularly annulated throughout, fairly stout except at the proximal ends where they taper gradually to their point of origin; distal ends of many of the branches bear a more or less regular whorl, or radiating cluster, of annulated branchlets just below the hydranth body, reminding one of the whorls of cirri around the stems of the stalked crinoids. Hydranths large, with long, slender body and proboscis and numerous (20-35) capitate tentacles arranged in a scattered or sub-verticillate manner over nearly the whole surface.

**Gonosome.**—Gonophores very numerous, borne among the tentacles on the hydranth bodies, globular in outline and showing no traces of radial canals or other medusoid structures. The specimens secured were females and the gonophores were packed full of developing ova.

**Distribution.**—All the specimens were secured in Yakutat Bay, Alaska, by Dr. W. R. Coe of the Harriman Expedition.

This interesting species seems to be nearest to *C. pusilla* Gaertner, if Allman has properly identified that species. It differs from other members of the genus in the curious whorl of short branchlets which bear neither hydranths nor gonophores and are situated a short distance below the terminal hydranth of the stem or branch to which they are attached. Another character not shown in the figures of this genus published by Hincks and Allman, is the narrowing at the proximal ends of the stems and branches. The specimens were found immersed in sponge so far that only the hydranths extended above the surface of the sponge.

SYNCORYNE.

**Trophosome.**—Characters the same as those given for the family.

**Gonosome.**—Reproductive elements produced in free medusae with a long manubrium and four marginal tentacles, each having a sense bulb with an eye-spot at its base.
SYNCORYNE EXIMIA Allman.

(Plate xiv, figs. 3, 4.)

This appears to be the first record of the occurrence of this species in American waters. There are many specimens in the collection, but all are from the same locality.

Distribution.—Juneau, Alaska (Harriman Expedition); Great Britain (Allman and Hincks); Lofoten Islands, Norway (Sars).

Family BIMERIDÆ.

Trophosome.—Hydranths with a conical or domé-shaped proboscis, around the base of which is a whorl of filiform tentacles.
Gonosome.—Sexual products developed in fixed sporosacs.

GARVEIA.

Trophosome.—Colony branched; perisarc conspicuous.
Gonosome.—Gonophores borne on distinct branchlets which have a chitinous investment ending in a cup-like expansion just below the gonophore.

GARVEIA NUTANS Wright.

This is another species that has not before been reported from American waters. The specimens were fragmentary, making the identification somewhat uncertain, although I have little doubt of its correctness.

Distribution.—Berg Inlet, Glacier Bay, Alaska. (Harriman Expedition.) Originally described from the British Coast.

GARVEIA ANNULATA sp. nov.

(Plate xv, figs. 1, 2.)

Trophosome.—Colony attaining a height of 1½ inches, consisting of a number of closely aggregated and sparingly and irregularly branched stems. Stems strongly and evenly annulated throughout, the perisarc expanding distally into thin chitinous pseudo-hydrothecæ which cover the hydranth body nearly to the level of the tentacles. Hydranths with
a conical, or rather conoid, proboscis and about sixteen tentacles all of which appear to be held more or less erect.

**Gonosome.**—Gonophores borne either on the stem or hydorhiza, more frequently the latter, oval in shape, borne on pedicels enveloped in a chitinous perisarc which ends in a slightly expanded collar a little below the gonophore. The specimens collected were female and the gonophores were packed with apparently mature ova.

**Color.**—The label accompanying the specimens bore the following statement: "Bright orange throughout, heads, stems and all."

**Distribution.**—Yakutat and Sitka, Alaska. Collected by the Harriman Expedition in considerable quantities.

This species can be sharply distinguished from its British relative by the very distinct and beautiful annulation which covers the entire stem and branches. It is much less extensively branched than the British species, and the gonophores are more generally borne on the roots.

The structure that I have designated above as a 'pseudo-hydrotheca' is of considerable morphological interest, for it may throw light on the origin of the hydrotheca. The extension of the chitinous perisarc of the stem over the body of the hydranth appears to be attached to the latter. A true hydrotheca would be formed if the perisarc around the hydranth body should become thicker and detached.

**Family EUDENDRIDAE.**

**Trophosome.**—Colony branching. Hydranths with a single whorl of filiform tentacles and a trumpet-shaped or hemispherical proboscis which is expanded distally and contracted proximally, thus being sharply distinguished from the hydranth body.

**Gonosome.**—Reproductive elements developed in fixed sporosacs attached to a usually more or less degenerated hydranth body below the tentacles.

This family contains but one genus, *Eudendrium*, which needs no further definition.

**EUDENDRIUM VAGINATUM** Allman.

(Plate xv, figs. 3-6.)

As the gonosome of this species has not heretofore been described, the following is inserted here:

**Gonosome.**—Gonophores (female) in dense clusters around the bodies of hydranths that are usually devoid of tentacles. Each gono-
NUTTING

phore is borne on a pedicel which resembles those of Garveia, having a distinct expanded collar a short distance below the hydranth.

**Distribution.**—Sitka Harbor and Yakutat, Alaska, abundant (Harri- 
man Expedition); Shetland Island, Scotland (Allman).

This beautiful species bears considerable resemblance to Euden-

drium annulatum Allman, especially in its gonosome which Allman 

describes as follows: "The gonophores are grouped in clusters, con-

sisting of from eight to twenty egg-shaped bodies attached around the 

axis of gonoblastidea, which are of moderate length."¹

Were it not for a peculiar character of the trophosome, i. e., the ex-

panded pseudo-hydrotheca investing the body below the tentacles much 

as in Garveia, there might be some suspicion that E. vaginatum and 

E. annulatum are synonyms, particularly in view of the fact that both 

were described from the Shetland Islands.

It also seems not improbable that Eudendrium pygmaeum Clark² 

may be another synonym of E. vaginatum, as Clark's description of 

the gonosome agrees well with the gonosome described above. If 

this be true, it is also likely that the dried stems described by Clark 

from Santa Cruz, California, will be found to belong to this same 

species.

**Family TUBULARIDÆ.**

**Trophosome.**—Hydranths large, with a basal whorl of filiform ten-

tacles and a distal set of closely crowded shorter filiform tentacles.

**Gonosome.**—Reproductive elements developed in sessile medusae 

borne in clusters just above the basal tentacles and producing actinules 

instead of planulae.

**TUBULARIA.**

The only genus included in the family in the sense here used.

**TUBULARIA HARRIMANI** sp. nov.

(Plate xvi.)

**Trophosome.**—Stem usually unbranched, attaining a height of 1½ 

inches, irregularly and sparingly annulated and increasing in size from 

the proximal to the distal end, but more rapidly on the basal portion; 

a marked constriction some distance below the hydranth body; stem 

canaliculated between the constriction and the hydranth. Hydranth 

with forty to fifty basal tentacles and about twenty in the distal set.

**Gonosome.**—Gonophores borne in about twelve very long and 

densely crowded racemes, which are supported by long, tentacle-like

pedicels arising above the proximal row of tentacles. Gonophores (female) with three to five long tentacular processes which are sometimes half the length of the gonophore. The actinule at birth is without a distal row of tentacles, and the gonophore has no indication of radial canals.

Exclusive of this species there have now been described four species of Tubularia from the Pacific Coast of North America; Parypha microcephala (A. Agassiz), which differs from the present species in having flattened, instead of round, tentacular processes to the gonophores; Tubularia elegans Clark, which has mere tubercles instead of the filiform processes to the gonophores; Tubularia borealis Clark, which differs in having laterally compressed processes to the gonophores; and Tubularia larynx Ellis and Solander (reported by Gary S. Calkins), which differs from T. harrimani in the number of both proximal and distal sets of tentacles, as well as in several other characters.

The species seems to be abundant at Orca, as numerous specimens were found.

**CALYPTEROBLASTE.**

Hydroida in which hydrothecae are developed for the protection of the hydranths and gonangia for the protection of the gonophores.

Family **CAMPANULARIDÆ**.

*Trophosome.*—Hydrothecae well developed, non-operculate, never adnate nor immersed in the stem and always with a septum partially dividing the hydrothecal cavity from the stem cavity. Hydranths usually with conical proboscis and a single whorl of filiform tentacles.

*Gonosome.*—Gonophores producing planulae or free medusae.

It would be hard to find two authorities who would agree as to the genera of this exceedingly perplexing family. The arrangement here adopted is substantially the same as that used by the writer in another work now in press. It is not offered as a final solution of the difficulty, but as a convenience in discussing the group in the present connection.

2 Transactions Conn. Acad. Sci., Vol. iii, p. 253, 1876.
5 Handbook of the Hydroids of the Woods Hole Region. To be published by the U. S. Fish Commission.
**CLYTIA.**

*Trophosome.*—Stem not regularly branched. Hydrothecae with toothed margins, or with excessively thick walls and with long pedicels.

*Gonosome.*—Reproduction by means of free medusae.

**CLYTIA CALICULATA** (Hincks).

(Plate xvii, figs. 1, 2.)

Some authors, as Levinsen, regard this species as identical with *C. integra* Macgillivray. The mode of reproduction is so different, however, that the two would go into different genera in the classification here adopted.

*Distribution.*—Yakutat, Alaska (Harriman Exped.); British Coast (Hincks); Spitsbergen (Marktanner-Turneretscher); New England Coast (Verrill); Puget Sound (Calkins).

**CLYTIA COMPRESSA** (Clark).

(Plate xvii, figs. 3, 4.)

*Distribution.*—Orca, Alaska (Harriman Exped.); Shumagin Islands (Clark). The figures given of this species well illustrate the great variation in thickness of the hydrothecal walls. All the specimens thus far discovered were found attached to Laminaria, over which they creep in great profusion.

Von Lendenfeld makes his *Eucopella campanularia* the subject of one of his masterly monographic papers and it appears to agree in every particular with the species under discussion. If I am correct in supposing the two species identical, the name *Eucopella campanularia* will become a synonym and a very exceptional distribution will be recorded for *Clytia compressa*. It is interesting to note that von Lendenfeld's species was also found growing on Laminaria.

The present writer does not agree with Calkins in his suggestion that *C. compressa* is a synonym of *C. caliculata*. 
CAMPANULARIA.

Trophosome.—Colony unbranched or regularly branched; stem simple or fascicled; hydrothecæ campanulate, never completely sessile nor with operculum.

Gonosome.—Gonophores producing planulae without the intervention of medusæ.

CAMPANULARIA VERTICILLATA (Linn.)
Campanularia verticillata Sars, Bidrag til Kundskabom om Norges Hydroider, p. 46, 1873.—VERRILL, Preliminary check-list of Marine Invertebrates of Atlantic Coast, p. 16, 1879.

Distribution.—Kadiak, Alaska (Harriman Exped.); North Cape, Norway (Sars); New England Coast (Verrill).

CAMPANULARIA DENTICULATA Clark.
Distribution.—Orca, Alaska (Harriman Exped.); Port Etches, Alaska (Clark).

CAMPANULARIA LINEATA Nutting.

Distribution.—Berg Inlet, Glacier Bay, Alaska (Harriman Exped.); Puget Sound (Nutting).

CAMPANULARIA RITTERI sp. nov.
(Plate xvii, fig. 5.)

Trophosome.—Colony usually consisting of unbranched pedicels growing directly from a creeping rootstock. Pedicels long and slender, usually with a single distinct annulation at the distal end just below the hydrotheca and about three less distinct ones at the proximal end, the middle portion not being annulated. Hydrothecæ cylindrical, large, delicate in structure and with a perfectly even rim.

Gonosome.—Unknown.

Distribution.—Juneau, Alaska, 20 fathoms. Collected by Prof. Wm. E. Ritter to whose efforts the fine series of Hydroids here discussed is so largely due, and for whom this species is named.

CAMPANULARIA SPECIOSA Clark.
(Plate xviii, fig. 3, Plate xix, fig. 3.)

Distribution.—Orca, Alaska (Harriman Exped.); Yukon Harbor, Big Koniuji, Shumagin Islands, Alaska (Clark); Japan Coast (Allman); Greenland (Levinsen).

CAMPANULARIA URCEOLATA Clark.
(Plate xvin, fig. 2.)

Distribution.—Yakutat Bay, Alaska (Harriman Exped.); Lituya Bay, Alaska (Clark).

The specimens collected by the Harriman Expedition were growing profusely over the stems and branches of Thuiaria costata in company with another parasitic species.

CAMPANULARIA REDUPLICATA sp. nov.
(Plate xviii, fig. 1.)

Trophosome.—Colony consisting of unbranched stems or pedicels springing from a creeping rootstock. Pedicels one to three times as long as the hydrothecae, and strongly annulated throughout. Hydrothecae deeply campanulate, thick-walled; margins armed with twelve to fourteen rather pointed teeth, and reduplicated once or twice, giving a striking and unusually ornate appearance.

Gonosome.—Gonangia roughly ovate, irregular in outline, with a short neck, small terminal aperture and a very short pedicel. They were empty in the specimens examined, so that it was impossible to ascertain whether they produced planulæ or medusæ.

Distribution.—Yakutat, Alaska (Harriman Exped.). All the specimens were found growing in a parasitic manner over colonies of Thuiaria costata, in company with Campanularia urceolata. The two species were often so intimately interwoven as they crept over the stems and branches of the sertularian that I, at first, thought them dimorphic forms of one species. However, in all cases careful dissection showed that they were entirely separate colonies. The reduplication of the hydrothecal margins seems to be a constant feature and adds peculiar beauty to this striking little campanularian.

CAMPANULARIA REGIA sp. nov.
(Plate xix, figs. 1, 2.)

Trophosome.—Colony consisting of a creeping rootstock without annulations, giving forth strong pedicels that are sometimes longer
than the hydrothecæ and sometimes considerably shorter, without a
definite swelling below the hydrothecæ. Hydrothecæ immense, in
one case nearly \( \frac{3}{2} \) of an inch in height, long, tubular-urceolate, ex-
panded distally, with slightly everted and broadly sinuous margin.
The margin is reduplicated in one specimen. Hydranth with about
twenty tentacles.

_Gonosome._—Not known.

_Distribution._—Orca, Prince William Sound, Alaska (W. R. Coe,
Harriman Exped.).

This species is closely allied to _C. grandis_ Allman,¹ and may be
identical with it although it differs from Allman's description in
the character of the pedicels which he describes as having distinct node-
like enlargements immediately below the hydrothecæ. The hydro-
thecæ are larger than those of any other campanularian known to me.
But one small colony was found and it was creeping over another
hydroid.

**OBELIA.**

_Trophosome._—Colony regularly branching; stem simple or com-
 pound. Hydrothecæ campanulate, thin, never with greatly thickened
walls.

_Gonosome._—Reproduction by means of medusæ which are disk-
shaped, with four radial canals, more than eight marginal tentacles,
eight interradial lithocysts and a short manubrium without mouth ten-
tacles.

**OBELIA DICHOTOMA (Linn.).**

_Sertularia dichotoma_ LINN., Systema Naturæ, Ed. x, p. 812. 1758.
_Obelia dichotoma_ SCHULZE, Nordsee Expedition, Hydroida, p. 129, 1872.—
_VERRILL, Preliminary check-list Marine Invertebrates of Atlantic coast,

_Distribution._—Sitka, Berg Inlet, and Orca, Alaska (Harriman
Exped.); British Coast (Hincks); Helgoland (Schulze); Puget
Sound (Calkins).

**OBELIA Plicata** Hincks.

_Obelia plicata_ HINCKS, British Hydroid Zoophytes, p. 159, 1868.—_NUTTING,
xxi, No. 13, p. 741, 1899.

_Distribution._—Orca, Alaska (Harriman Exped.); Puget Sound
(Nutting); British Coasts (Hincks).

¹Diagnoses of new Genera and Species of Hydroida; Linnaæan Soc. Jour.
OBELIA BOREALIS sp. nov.

(Plate xix, figs. 4, 6.)

_Trophosome._—Colony sometimes attaining a height of eighteen inches, but usually much shorter; stem not truly fascicled, although several stems may be interwoven, exceedingly long and slender, sinuous, giving off lateral branches in pairs on proximal portion and more often singly on distal portion; branches with a strong tendency to verticillate arrangement, forming oblique angles with the stem and divided into numerous branchlets in a flabellate manner. Pedicels short and completely annulated, or long and annulated only at ends, set on broad shoulders of the stem. Hydrothecæ funnel-shaped, the sides usually straight, aperture with an even rim. Hydranths not well preserved in specimens examined.

_Gonosome._—Gonangia borne in axils of branches and branchlets, oblong-ovate, truncated above, having a collar in mature specimens; aperture apparently very large, pedicels strongly annulated. The gonangia of the specimens examined were filled with developing medusæ of the regular Obelia type.

_Distribution._—Yakutat, Alaska (Harriman Exped.).

This fine species is related to _O. flabellata_, but the hydrothecæ are much deeper than in _O. flabellata_, in which they are sub-triangular in outline. It also bears some resemblance to _O. commissuralis_, which, however, is a much more delicate species, with smaller and more campanulate hydrothecæ.

OBELIA DUBIA sp. nov.

(Plate xx, fig. 1.)

_Trophosome._—Colony attaining a height of about 3/4 inch; stem sparingly branched, the main stem and larger branches sinuous or slightly geniculate, giving forth pedicels singly or in opposite pairs at the bends. Pedicels rather long and annulated throughout, the stem also more extensively annulated than in most species of the genus. Hydrothecæ very large, deep, tubular, with very shallow undulations around the margin, from between which lines run down for a short distance on the surface of the hydrothecæ.

_Gonosome._—Unknown.

_Distribution._—Orca, Alaska (Harriman Exped.).

This species bears some resemblance to _O. bidentata_ Clark, found on the New England Coast, but differs in the nature of the hydrothecal teeth which are mere sinuosities, instead of being mucronate with two denticles each as in the latter species.
HEBELLA.

Trophosome.—Pedicels arising from a creeping rootstock, very short. Hydrothecae tubular, with entire margins, without opercula, and having their cavities separated from those of the stems by a partial septum. Hydranths with a conical proboscis.

This genus was originally instituted by Allman. As here defined it includes several species heretofore included in the genus "Laëa."

HEBELLA POCILLUM (Hincks).

Distribution.—Kadiak, Alaska (Harriman Exped.); Nunivak Island, Alaska (Clark); Kara Sea (Bergh); British Coasts (Hincks); New England Coast (Verrill).

GONOTHYREA.

Trophosome.—Much as in Obelia.

Gonosome.—Planulæ produced in sessile medusaform gonophores which remain attached to the top of the gonangia until the spermatozoa or planulæ are discharged.

GONOTHYREA INORNATA sp. nov.

(Plate xx, figs. 2-4.)

Trophosome.—Colony attaining a height of about two inches and consisting of a main stem which almost immediately breaks up into a number of very slender, erect, almost straight branches which are ornamented with about three annulations immediately above the origins of the pedicels. Pedicels alternate, erect, much broader below than above and with seven to ten annulations. Hydrothecæ funnel-shaped, with entire margins.

Gonosome.—Gonangia borne in the axils of the pedicels, slender, obconic, with a tendency to annulation. Each gonangium contains a single sporosac which when mature rests upon the summit of the gonangium and has little indication of radial canals or tentacles.

Distribution.—Yakutat Bay, Alaska (Harriman Exped.).

This species differs from others of the genus in having but one sporosac to each gonangium and in the obliteration of most of the medusoid characters of the sporosac. The entire margin of the hydrotheca is also an exceptional character.

1 Allman, Challenger Report, Hydroida, Second Part, p. 29, 1888.
Family *CAMPANULINIDÆ*.

**Trophosome.**—Colonies branched or unbranched. Hydrothecæ borne on pedicels, tubular, ending in an operculum composed of several converging segments or triangular flaps. Hydranth with a conical proboscis.

**Gonosome.**—Gonangia producing free medusæ or planulae.

**CAMPANULINA.**

**Trophosome.**—Hydrothecæ thin-walled, the upper portion cleft so as to produce very long and slender teeth which form an operculum by the convergence of their free ends.

**Gonosome.**—Gonangia producing bell-shaped medusæ, with four radial canals, two or four marginal tentacles, and eight lithocysts.

**CAMPANULINA RUGOSA** sp. nov.

(Plate xxii, figs. 1, 2.)

**Trophosome.**—Colony attaining a height of about \( \frac{1}{2} \) inch. Stem irregularly branched; branches tending to an alternate arrangement, straggling, geniculate; stem and branches strongly and regularly annulated throughout. Pedicels very short, with three to six annulations. Hydrothecæ ovoid-oblong, the distal third being composed of the operculum consisting of ten or twelve segments. The hydranths have about sixteen tentacles.

**Gonosome.**—Gonangia in axils of the pedicels and branches, sometimes aggregated on certain branches to the exclusion of hydrothecæ. They are oblong-ovoid in shape and somewhat flattened on their distal ends. Each gonangium contains a single medusa when mature.

**Distribution.**—Juneau, Alaska (Harriman Exped.). The specimens were found growing on *Obelia*.

**CALYCELLA.**

**Trophosome.**—Stem a creeping rootstock sending forth short annulated pedicels. Hydrothecæ tubular, thick-walled, with opercula that are distinct from the hydrothecal teeth, and composed of several triangular segments.

**Gonosome.**—Gonangia borne on the rootstock, and, when mature, bearing acrocysts.

**CALYCELLA SYRINGA** (Linn.).

*Sertularia syringa* Linn., *Systema Naturæ*, Ed. xii, Tom. i, Pars ii, p. 1311, 1767.

Distribution.—Berg Inlet and Kadiak, Alaska (Harriman Exped.); Coal Harbor, Shumagin Islands, Alaska (Clark); Kara Sea (Bergh); British Coasts (Hincks); New England Coast (Verrill); Puget Sound (Nutting).

Family LAFœIDÆ.

Trophosome.—Hydrothecæ tubular, margins without teeth or opercula, the hydrothecal cavity not divided from the stem cavity by a partial septum.

Gonosome.—Gonangia forming a ’Coppinia’ mass.

LAFŒA.

Trophosome.—Colony with a fascicled stem, and with hydrothecæ either free or partially immersed in the stem, the distal portion not being abruptly turned upward.

Gonosome.—A ’Coppinia’ mass.

LAFŒA DUMOSA (Fleming).

Distribution.—Dutch Harbor, Unalaska (Harriman Exped.); Port Etches, Alaska (Clark); North Cape, Norway (Sars); British Coast (Hincks); New England Coast (Verrill); Puget Sound (Nutting); California Coast (Clark).

LAFŒA GRACILLIMA (Alder).

Distribution.—Juneau, Berg Inlet and Orca, Alaska (Harriman Exped.); Shumagin Islands, Alaska (Clark); British Coast (Alder);
Spitzbergen (Marktanner-Turneretscher); New England Coast (Verrill); Puget Sound (Nutting).

LAFŒA FRUTICOSA M. Sars.

_Distribution._—Juneau, Berg Inlet and Kadiak, Alaska (Harriman Exped.); Kiska Harbor, Shumagin Islands, Alaska (Clark); British Coasts (Hincks); Lofoten, Norway (G. O. Sars); New England Coast (Verrill); Puget Sound (Nutting, MSS.).

LAFŒA ADHÆRENS sp. nov.

(Plate xxi, figs. 3, 4.)

_Trophosome._—Colony forming an encrusting mass of adherent root-stocks disposed both longitudinally and transversely over colonies of other Hydroids, the tubes of the rootstock intertwined much like the threads of a fabric. Hydrothecæ sessile, tubular, often more or less curved, aperture facing upward, entire; margin slightly expanded. The hydrothecæ are very irregularly disposed, being much more crowded in some places than in others.

_Gonosome._—The ‘Coppinia’ mass is much like that of _Lafœa dumosa_, being composed of closely packed gonangia interspersed with long, tubular, variously curved modified hydrotheca. The gonangia are flask-shaped, with a tubular neck and small aperture. Each gonangium apparently contains a single ovum.

_Distribution._—Kadiak Harbor, Alaska. Growing over stems of _Thuiaria turgida_ (Harriman Exped.).

This interesting species is so different in appearance from the others of the genus that I was at first inclined to make it the type of a new genus.

GRAMMARIA.

_Trophosome._—Stem fascicled, composed of an axial tube from which the hydrothecæ spring and to which they are partly adnate, completely enclosed by a definite number of peripheral nonhydrothecate tubes.

_Gonosome._—A ‘Coppinia’ mass.

GRAMMARIA IMMERSA sp. nov.

(Plate xxi, figs. 5, 6.)

_Trophosome._—Stem rigid, erect, giving forth scattered, stiff and straight, alternate branches forming nearly a right angle with the stem.
Height of a fragmentary specimen about $\frac{3}{4}$ inch. Stem and branches sharply constricted proximally, composed of an axial tube which gives off the eight or nine series of hydrothecae, and a number of peripheral tubes enclosing the axial tube completely, thus burying all the hydrothecae nearly to their distal ends. Hydrothecae arranged in about eight or nine longitudinal series, forming spirals. The distal ends of the hydrothecae are abruptly bent outward, so that the round, even aperture is vertical. When the peripheral tubes are removed the hydrothecae are seen to be long, tubular, doubly curved, narrowing proximally, but without true pedicels, and all springing from the axial tube.

**Gonosome.**—Unknown.

**Distribution.**—St. Paul harbor, Kadiak (Harriman Exped.).

**FILELLUM.**

**Trophosome.**—Stem a creeping, slender rootstock, parasitic on other hydroids, often forming a reticulate structure. Hydrothecae curved, decumbent, and partly adherent; margin entire, without operculum.

**Gonosome.**—A 'Coppinia' mass.

**FILELLUM SERPENS** (Hassell).

*Campaenaria serpens* Hassell, Zoologist, No. 69, p. 2223.

*Filellum serpens* Sars, Bidrag til Kundskaben om Norges Hydroider, p. 29, 1873.—Verrill, Preliminary Check-list Marine Invertebrates of Atlantic Coast, p. 17, 1879.

**Distribution.**—Juneau, Alaska (Harriman Exped.); British Coast (Hassell); Lofoten, Norway (Sars).

Family **HALECIDÆ.**

**Trophosome.**—Hydrothecae reduced to the form of saucer-shaped or collar-like hydrophores, usually borne on broad tubular pedicels; margins even, often reduplicated. Hydranths large, incapable of retracting within the hydrophores, and with a conical or dome-shaped proboscis.

**Gonosome.**—Gonangia producing planulae, and usually differing in the two sexes.

**HALECUM.**

**Trophosome.**—No specialized defensive 'persons' developed.

**Gonosome.**—Female gonangia often surmounted by a pair of hydranths.

**HALECUM HALECINUM** (Linn.).

*Sertularia halecina* Linn., Systema Naturae, Ed. x, p. 809, 1758.

Distribution.—Kadiak, Alaska (Harriman Exped.); British Coast (Hincks); Greenland (Marktanner-Turneretscher); New England Coast (Verrill); Puget Sound (Nutting).

HALECium Muricatum (Ellis and Solander).

Distribution.—Orca, Alaska (Harriman Expd.); British Coasts (Ellis and Solander); Greenland (Levinsen); New England Coast (Verrill).

HALECium Scutum Clark.

Distribution.—Berg Inlet and Yakutat, Alaska (Harriman Expd.); Unalaska (beach) and Shumagin Islands, Alaska (Clark); North Cape, Norway (Bonnevie).

HALECium Reversum sp. nov.

(Plate xxiii, figs. 1, 2.)

Trophosome.—Colony attaining a height of about one inch. Main stem fascicled, branches simple and alternate, making a flabellate colony. Nonfascicled part of the stem and branches divided into internodes, each of which bears one or two pedicels springing from its proximal portion. Pedicels long, of even diameter throughout, often rugose on proximal portion. Hydrophores with large everted margins and a distinct row of dots. Reduplication of margins distant, when present. Hydranth small for this genus, with about twenty tentacles.

Gonosome.—Not present in type specimen.

Distribution.—Juneau, Alaska (Harriman Exped.).

This species possesses the very exceptional, if not unique, character of having the pedicels spring from the proximal part of the internode instead of the distal portion, as in all other species of Halecium with which I am acquainted. This character appears to be constant. The specimen was dredged from a depth of twenty fathoms.
HALECİUM ORNATUM sp. nov.
(Plate xxii, figs. 3, 4.)

_Trophosome._—Colony parasitic, branching irregularly. Stems not fascicled, the stem and branches sparsely and irregularly annulated. Pedicels long, of equal diameter throughout. Hydrophores with broad, everted margins, occasionally reduplicated. Hydranth large, with twenty-four to thirty tentacles.

_Gonosome._—A single apparently young gonangium was borne on a pedicel just below the hydrophore. It was in form a truncated and deeply annulated cone. Probably the mature gonangium would resemble that found in the next species.

_Distribution._—Berg Inlet, Glacier Bay, Alaska. Growing on _Lafwa gracillima_ (Harriman Exped.).

HALECİUM SPECIOSUM sp. nov.
(Plate xxii, figs. 1, 2.)

_Trophosome._—Colony small, attaining a height of about \( \frac{3}{4} \) inch. Stem not fascicled, the main stem and branches apparently formed of series of stout pedicels, each giving origin to another pedicel just below the hydrophore. The pedicels thus take the place of stem joints, bending alternately to the right and left, giving a geniculate appearance to the series. Pedicels broad, corrugated proximally and smooth distally. Hydrophores large, with broadly expanded but not everted margins, and a well marked row of dots. There appears to be no reduplication of the margins. Hydranths very large with twenty-four to thirty short tentacles, a broad oral disk occupied by the low dome-shaped proboscis.

_Gonosome._—Gonangia borne on rather long annulated pedicels below the hydrophores, particularly on the upper part of the colony; regularly ovoid in outline, and evenly and beautifully annulated throughout.

_Distribution._—Yakutat Bay, Alaska (Harriman Exped.).

This is the most strikingly ornamented species of _Halecium_ known to the writer. Its manner of growth is exceptional, although not unknown among its allies, and the hydranth is more like the polyp of some actinozoon than of a hydroid. The gonangia are beautiful structures. They seemed to be filled with a granular, ovoid mass, probably a single large sporosac.
HALECIUM ROBUSTUM sp. nov.  
(Plate xxin, figs. 3, 4, 5.)

*Trophosome.*—Stem very thick and fascicled, consisting of an immense number of wavy tubes. In the single specimen collected, the main stem divides near its base into three heavy fascicled branches, which themselves branch and subdivide extensively, the fasciculation continuing nearly to the tips of the branches. The entire height of the colony is about three inches. The branching is so profuse that the arrangement of the internodes is obscure. The ultimate branches give off short pedicels and sessile hydrophores in what appear to be clusters or whorls. Pedicels short, tubular, ending in an exceedingly shallow hydrophore. Hydrophores reduced to a mere narrow rim, marked by the internal diaphragm and circlet of dots, the only distinction between pedicel and hydrophore, as the margin of the latter is not appreciably everted. Most of the hydrophores are sessile, being set on mere shoulders of the branch from which they grow. The circlet of dots can only be made out with great difficulty and the use of high magnification. Hydranths exceedingly numerous and large, covering the branches so as to almost entirely conceal them from view. Tentacles about twenty, surrounding a low conoid proboscis.

*Gonosome.*—Unknown.

*Distribution.*—Berg Inlet, Glacier Bay, Alaska (Harriman Exped.).

This species bears some relation to *Halecium densum* Calkins, 1 but differs from that species in the hydrophores, which are not reduplicated and have straight, not everted, margins. The hydranths are so crowded that a branch resembles an expanded colony of Alcyonaria, and appears to be made up entirely of hydranths.

Family *SERTULARIDÆ.*

*Trophosome.*—Hydrothecæ sessile, more or less adnate by their side to the stem and branches upon which they grow; always in more than one longitudinal row on each branch, the arrangement usually biserial. Hydranth with a conical proboscis.

*Gonosome.*—Reproduction always by means of planulae, which are developed within the gonangia. No medusæ.

*SERTULARELLA.*

*Trophosome.*—Stem and branches divided into regular internodes, each bearing one or two hydrothecæ; nodes oblique. Hydrothecæ

---

THE HYDROIDS

alternate, borne on opposite sides of the stem and branches. Margin usually more or less toothed, aperture usually provided with an operculum consisting of more than one segment.

SERTULARELLA TRICUSPIDATA (Alder).

Distribution.—Juneau, Berg Inlet, and Yakutat, Alaska (Harriman Exped.); Shumagin Islands, Semidi Islands, Unalaska, Port Etches, and Kiska Harbor, Alaska (Clark); British Coast (Alder); New England Coast (A. Agassiz); Greenland (Marktanner-Turneretscher); Puget Sound (Nutting).

SERTULARELLA POLYZONIAS (Linn.).

Sertularia polyzonias LINN., Systema Naturae, Ed. x, p. 813, 1758.

Distribution.—Orca, Alaska (Harriman Exped.); Port Etches and Nunivak Island, Alaska (Clark); British Coasts (Gray); North Cape, Norway (Sars); New England Coast (Agassiz); Puget Sound (Calkins).

Calkins, in the reference cited above, identifies a small specimen otherwise identical with S. polyzonias, as the species S. conica Allman, and says: "The only character, and that a small one, by which to distinguish it from the very wide-spread S. polyzonias is the well-marked wrinkling on the adcauline side of the hydrotheca." Specimens from Alaska in the Harriman Collection, agreeing with Calkins's description and figures, have the characteristic gonosome of S. polyzonias, and I therefore consider that I am justified in regarding his specimen as belonging to that species.

SERTULARELLA SACCATA sp. nov.

(Plate xxiv, figs. 1-3.)

Sertularella geniculata Marktanner-Turneretscher, Die Hydroiden Des k. k. naturhistorischen Hofmuseums, p. 222, 1890.

Trophosome.—Colony consisting of a sparingly branched, non-fascicled stem attaining a height of about one inch. Stem annulated and nonhydrothecate proximally, otherwise bearing alternate hydrothecae, one to each internode; stems and branches erect. Hydrothecae roughly ovate in general outline, with a laterally inclined, broad, smooth, round neck or collar surmounted by a four-toothed aperture and a four-flapped operculum; below the neck the body of the hydrotheca has three or four broad annular corrugations. Hydranths with about sixteen tentacles.

Gonosome.—Gonangia large, oblong-ovate in general outline, with several, seven to nine, broad annular corrugations. The mature ova are enclosed in an ovoid acrocyst resting on the top of the gonangium.

Distribution.—Popof Island, Alaska (Harriman Expd.); Unalaska, Shumagin Islands, St. Paul Island and Nunivak Island, Alaska (Clark); Jan Mayen (Marktanner-Turneretscher).

The specimens of this species secured by the Harriman Expedition agree well with the figure given by Clark of specimens that he identified as S. rugosa. The very conspicuous neck, however, would seem to be sufficient to distinguish S. saccata from S. rugosa, and the same difference exists between the gonangia of the two forms. The figure given by Marktanner-Turneretscher for S. geniculata Hincks differs greatly from Hincks’s original description and figure, and agrees well with the present species, except that the hydrothecae are more closely approximated in the latter.

THUIARIA.

Trophosome.—Colony branched, the branches divided into unequal internodes, each bearing several pairs of opposite or subopposite hydrothecae. Hydrothecae usually deeply immersed in the stem or branch to which they are attached. The branches are alternate, and each springs from an unpaired hydrotheca.

Gonosome.—Much as in Sertaria.

THUIARIA ARGENTEA (Ellis and Solander).

Distribution.—Yakutat, Alaska (Harriman Exped.); British Coast (Ellis and Solander); Kara Sea (Bergh); New England Coast (Verrill); Puget Sound (Nutting); California (Clark).

THUIARIA SIMILIS (Clark).

Distribution.—Berg Inlet, Glacier Bay, Alaska (Harriman Exped.); Hagmeister Island, Alaska (Clark); Puget Sound (Nutting, MSS.).

THUIARIA VARIABILIS (Clark).

Distribution.—Orca, Alaska (Harriman Exped.); numerous stations in Alaska (Clark); San Miguel Island, California (Clark); Puget Sound (Nutting, MSS.).

THUIARIA CUPRESSOIDES (Clark).

Distribution.—Yakutat, Alaska (Harriman Exped.); Shumagin Islands and Port Moller, Alaska (Clark).

THUIARIA COEI sp. nov.

(Plate xxvi, figs. 1–3.)

Trochosome.—Colony consisting of a single flexuous stem giving forth regularly alternate branches. Stem three inches high, and divided into irregular internodes each bearing a branch and two hydrothecae on one side and one hydrotheca on the other. Branches divided into irregular internodes, each usually bearing several pairs of hydrothecae. Hydrothecae subopposite, turgid basally, narrowing distally to a horizontal aperture which is pointed on its outer side. An upward projecting point of chitine at the bottom of each hydrotheca.

Gonosome.—Gonangia top-shaped, or obconical, with a pronounced round collar and rather broad aperture. Proximal portion broadly corrugated, and narrowing basally to a short curved pedicel.

Distribution.—Dutch Harbor, Alaska (W. R. Coe, Harriman Exped.).

This is a very distinct species, and the top-shaped gonangia are quite different from any others of the genus that I have seen.

THUIARIA FABRICII (Levinsen).

(Plate xxiv, figs. 4, 5.)

Distribution.—Dutch Harbor, Alaska (Harriman Exped.); Greenland (Levinsen); Puget Sound (Calkins).

A specimen in the Harriman collection agrees perfectly with the descriptions and figures of both Levinsen and Calkins. I have directly compared it with specimens of Sertularia argentea from England, and find that the two species are evidently distinct, T. fabricii differing from S. argentea in the following particulars. The colony is much more bushy in appearance, and more compactly branched. The hydrothecae are more nearly in pairs, and much more closely approximated, are more densely corneous and have a more delicate and less clearly defined aperture. The gonangia are considerably larger and of thinner texture, and are only occasionally armed with lateral spines.

It should be explained that Levinsen regards his Sertularia fabricii as identical with the Sertularia argentea of authors, and gives it the name S. fabricii. My opinion is that the species is distinct, and I recognize the name given by him because he has correctly described and figured the species, although not classing it as distinct. It should, however, be placed in the genus Thuiaria, for it comes well within that genus as here defined.

THUIARIA TURGIDA Clark.

(Plate xxv, figs. 4-6.)

Distribution.—Sitka, Orca, Popof Island, and Dutch Harbor, Alaska (Harriman Exped.); Port Etches, Shumagin Islands, Semidi Islands, and many other points in Alaska (Clark).

THUIARIA GIGANTEA Clark.

Distribution.—Kadiak and Popof Island, Alaska (Harriman Exped.); St. Paul Island, Hagmeister Island, Unalaska and Kiska Harbor, Alaska (Clark); St. Paul Island (Nutting).

THUIARIA THUIARIOIDES (Clark).

Distribution.—Yakutat, Alaska (Harriman Exped.); Nunivak Island and Chignik Bay, Alaska (Clark).
THUIARIA ELEGANS sp. nov.

(Plate xxv, figs. 1-3.)

**Trophosome.**— Colony consisting of a central nonfascicled stem branching in a plumose manner and attaining a height of about six inches. Stem bearing hydrothecæ throughout its length, divided by oblique nodes into long and irregular internodes, each of which usually bears three or four branches; branches alternate, pinnately arranged, unbranched proximally, and distally dividing into a number of branchlets; internodes of stem irregular, but each bearing normally more than one pair of hydrothecæ. Hydrothecæ subalternate, short, pitcher-shaped, with a double curve in front and an even aperture much like the top of a pitcher; operculum composed of a single flap.

**Gonosome.**— Gonophores borne on the upper sides of the distal ends of the branches in a closely set double row. The individual gonangium is slender, oblong-oval, with a truncated top, an internal distal plug which appears as a dark collar, and an internal mass of developing sex elements.

**Distribution.**—Berg Inlet, Glacier Bay, 20 fathoms; Dutch Harbor, Alaska (Harriman Exped.).

THUIARIA COSTATA sp. nov.

(Plate xxvi, figs. 4-9.)

**Trophosome.**— Colony usually a single stem giving forth alternate branches, the whole having a plumose appearance, stem simple, straight, the lower part composed of regular internodes, each bearing a pair of subopposite hydrothecæ, the upper part divided into regular internodes, each bearing a branch and three hydrothecæ; nodes oblique. Branches alternate and themselves branching dichotomously, divided into unequal internodes, each bearing more than two subopposite hydrothecæ. Hydrothecæ turgid below and narrowing above into a short neck which ends in a round aperture facing upward. A chitinous spine projects downward from the lower inner side of each hydrotheca.

**Gonosome.**— Gonangia borne profusely on both faces of the stem and often on the proximal ends of the branches; oblong-ovate, with a short, small neck and round terminal aperture, the gonangia are ornamented with about five compressed longitudinal ridges, the crests of which are colored black. General color of the gonangia orange brown.

**Distribution.**—Yakutat, Alaska. Abundant (Harriman Exped.).

This species resembles *Sertularia inconstans* Clark, but differs considerably, particularly in its gonosome, which is very strongly marked.
Family *PLUMULARIDÆ*.

*Trophosome.*—Hydrothecæ cup-shaped, usually more or less adnate to the stem or branches, and always arranged on one side only of the hydrocladia, or branches, on which they grow. Nematophores present.  
*Gonosome.*—Reproduction by means of planulae. No medusae.

**PLUMULARIA.**

*Trophosome.*—Hydrocladia unbranched alternate, nematophores on slender pedicels; hydrothecæ without marginal teeth. Stem not canal-  
*Gonosome.*—Gonangia oval, without corbulæ or protective structures of any kind.

**PLUMULARIA LAGENIFERA** Allman.

*Distribution.*—Berg Inlet, Popof Island, Alaska (Harriman Exped.); Puget Sound (Nutting); Coast of California (Nutting).

**PLUMULARIA PALMERI** Nutting.

*Plumularia palmeri* NUTTING, American Hydroïda, Part i, The Plumularidæ, p. 65, 1900.  

*Distribution.*—Victoria, B. C. (Harriman Exped.); San Diego. California (Nutting).  

This is the only species in the collection that was not from Alaska. It seemed best to include it in the list, particularly as a new locality is thereby noted.
BIBLIOGRAPHY.

The following list includes all the publications referred to in this Report on Hydroida. It does not include papers that were consulted and found to contain nothing pertinent to the immediate subject of the report.

2. Lateral view of hydrotheca (enlarged).
4. *Thuiaria costata* Nutting. Part of main stem, showing origin of branches (enlarged).
5. Front view of terminal branches (enlarged).
6. Two pairs of hydrothecae (greatly enlarged).
7, 8, 9. Gonangia (enlarged).
ALASKA HYDROIDS
INDEX

New genera and species and the pages on which they are described are in black-face type; synonyms in parenthesis; pages where synonymy of known species or genera is given in italics; subspecies are treated as species for the purposes of the Index.

Acanthinula 21
  aculeata 21
